Abstract We study the thermal properties of a pinned disordered harmonic chain weakly perturbed by a noise and an anharmonic potential. The noise is controlled by a parameter $\lambda \rightarrow 0$, and the anharmonicity by a parameter $\lambda' \leq \lambda$. Let κ be the conductivity of the chain, defined through the Green–Kubo formula. Under suitable hypotheses, we show that $\kappa = \mathcal{O}(\lambda)$ and, in the absence of anharmonic potential, that $\kappa \sim \lambda$. This is in sharp contrast with the ordered chain for which $\kappa \sim 1/\lambda$, and so shows the persistence of localization effects for a non-integrable dynamics.

1 Introduction

The mathematically rigorous derivation of macroscopic thermal properties of solids, starting from their microscopic description, is a serious challenge [8, 17]. On the one hand, numerous experiments and numerical simulations show that, for a wide variety of materials, the heat flux is related to the gradient of temperature through a simple relation known as Fourier’s law:

$$J = -\kappa(T) \nabla T,$$

where $\kappa(T)$ is the thermal conductivity of the solid. On the other hand, the mathematical understanding of this phenomenological law from the point of view of statistical mechanics is still lacking.

A one-dimensional solid can be modelled by a chain of oscillators, each of them being possibly pinned by an external potential, and interacting through a nearest neighbour coupling. The case of homogeneous harmonic interactions can be readily analysed, but it has been realized that this very idealized solid behaves like a perfect conductor, and so violates Fourier's law [21]. To take into account the physical observations, it is thus needed to consider more elaborate models, where ballistic transport of energy is broken. Here are two possible directions.

On the one hand, adding some anharmonic interactions can drastically affect the conductivity of the chain [2, 19]. Unfortunately, the rigorous study of anharmonic chains is in general out of reach, and even numerical simulations do not lead to completely unambiguous conclusions. In order to draw some clear picture, anharmonic interactions are mimicked in [3, 6] by a stochastic noise that preserves total energy and possibly total momentum. The thermal behaviour of anharmonic solids is, at a qualitative level, correctly reproduced by this partially stochastic model. By instance, the conductivity of the one-dimensional chain is shown to be positive and finite if the chain is pinned, and to diverge if momentum is conserved.

On the other hand, another element that can affect the conductivity of a harmonic chain is impurities. In [22] and [10], an impure solid is modelled by a disordered harmonic chain, where the masses of the atoms are random. In these models, localization of eigenmodes induces a dramatic fall off of the conductivity. In the presence of everywhere onsite pinning, it is known that the chain behaves like a perfect insulator (see Remark 1 after Theorem 1). The case of unpinned chain is more delicate, and turns out to depend on the boundary conditions [14]. The principal cases have been rigorously analysed in [24] and [1].

The thermal conductivity of an harmonic chain perturbed by both disorder and anharmonic interactions is a topic of both practical and mathematical interest. We will in the sequel only consider a one-dimensional disordered chain with everywhere on-site pinning. Doing so we avoid the pathological behaviour of unpinned one-dimensional chains, and we focus on a case where the distinction between ordered and disordered harmonic chain is the sharpest. We will consider the joint action of a noise and an anharmonic potential ; we call λ the parameter controlling the noise, and λ' the parameter controlling the anharmonicity (see Sect. 2.1 below).

The disordered harmonic chain is an integrable system where localization of the eigenmodes can be studied rigorously [16]. However, if some anharmonic potential is added, very few is known about the persistence of localization effects. In [13], it is shown through numerical simulations that an even small amount of anharmonicity leads to a normal conductivity, destroying thus the localization of energy. In [20], an analogous situation is studied and similar conclusions are reached. This is confirmed rigorously in [5], if the anharmonic interactions are replaced by a stochastic noise preserving energy. Nothing however is said there about the conductivity as $\lambda \rightarrow 0$. Later, this partially stochastic system has been studied in [12], where numerical simulations indicate that $\kappa \sim \lambda$ as $\lambda \rightarrow 0$.

Let us mention that, although the literature on the destruction of localized states seems relatively sparse in the context of thermal transport, much more is to find in that of Anderson's localization and disordered quantum systems (see [4] and references in [4, 12]). There as well however, few analytical results seem to be available. Moreover, the interpretation of results from these fields to the thermal conductivity of solids is delicate, in part because many studies deal with systems at zero temperature: the time evolution of an initially localized wave packet.

The main goal of this article is to establish that disorder strongly influences the thermal conductivity of a harmonic chain, when both a small noise and small anharmonic interactions are added. We will always assume that $\lambda' \leq \lambda$, meaning that the noise is the dominant perturbative effect. Our main results, stated in Theorems 1 and 2 below, are that $\kappa = \mathcal{O}(\lambda)$ as $\lambda \rightarrow 0$, and that $\kappa \sim \lambda$ if $\lambda' = 0$. Strictly speaking, our results do not imply anything about the case where $\lambda' > 0$ and $\lambda = 0$. However, in the regime we are dealing with, the noise is expected to produce interactions between localized modes, and so to increase the conductivity. We thus conjecture that $\kappa = \mathcal{O}(\lambda')$ in this later case. This is in agreement with numerical results in [20], where it is suggested that κ could even decay as $e^{-c/\lambda'}$ for some $c > 0$.

In the next section, we define the model studied in this paper, we state our results and we give some heuristic indications. The rest of the paper is then devoted to the proof of Theorems 1 and 2. Let us already indicate its main steps. The principal computation of this article consists in showing that the current due to harmonic interactions between particles k and $k + 1$, called $j_{k,har}$, can be written as $j_{k,har} = -A_{har}u_k$, where u_k is localized near k , and where A_{har} is the generator of the harmonic dynamics. This is stated precisely and shown in Sect. 4; the proof ultimately rests on localization results first established by Kunz and Souillard (see [16] or [11]). Once this is seen, general inequalities on Markov processes allow us to obtain, in Sect. 3, the desired upper bound $\kappa = \mathcal{O}(\lambda)$ in presence of both a noise and non-linear forces. The lower bound $\kappa \geq c\lambda$, valid when $\lambda' = 0$, is established by means of a variational formula (see [23]), using a method developed by the first author in [5]. This is carried out in Sect. 6.

2 Model and results

2.1 Model

We consider a one-dimensional chain of N oscillators, so that a state of the system is characterized by a point

$$x = (q, p) = (q_1, \dots, q_N, p_1, \dots, p_N) \in \mathbb{R}^{2N},$$

where q_k represents the position of particle k , and p_k its momentum. The dynamics is made of a hamiltonian part perturbed by a stochastic noise.

The Hamiltonian. The Hamiltonian writes

$$\begin{aligned}
 H(q, p) &= H_{har}(q, p) + \lambda' H_{anh}(q, p) \\
 &= \frac{1}{2} \sum_{k=1}^N \left(p_k^2 + v_k q_k^2 + (q_{k+1} - q_k)^2 \right) + \lambda' \sum_{k=1}^N \left(U(q_k) + V(q_{k+1} - q_k) \right),
 \end{aligned}$$

with the following definitions.

- The pinning parameters v_k are i.i.d. random variables whose law is independent of N . It is assumed that this law has a bounded density and that there exist constants $0 < v_- < v_+ < \infty$ such that

$$\mathbb{P}(v_- \leq v_k \leq v_+) = 1.$$

- The value of q_{N+1} depends on the boundary conditions (BC). For fixed BC, we put $q_{N+1} = 0$, while for periodic BC, we put $q_{N+1} = q_1$. For further use, we also define $q_0 = q_1$ for fixed BC, and $q_0 = q_N$ for periodic BC.
- We assume $\lambda' \geq 0$. The potentials U and V are symmetric, meaning that $U(-x) = U(x)$ and $V(-x) = V(x)$ for every $x \in \mathbb{R}$. They belong to $C_{temp}^\infty(\mathbb{R})$, the space of infinitely differentiable functions with polynomial growth. It is moreover assumed that

$$\int_{\mathbb{R}} e^{-U(x)} dx < +\infty \quad \text{and} \quad \partial_x^2 U(x) \geq 0,$$

and that there exists $c > 0$ such that

$$c \leq 1 + \lambda' \partial_x^2 V(x) \leq c^{-1}.$$

For $x = (x_1, \dots, x_d) \in \mathbb{R}^d$ and $y = (y_1, \dots, y_d) \in \mathbb{R}^d$, let $\langle x, y \rangle = x_1 y_1 + \dots + x_d y_d$ be the canonical scalar product of x and y . The harmonic hamiltonian H_{har} can also be written as

$$H_{har}(q, p) = \frac{1}{2} \langle p, p \rangle + \frac{1}{2} \langle q, \Phi q \rangle,$$

if we introduce the symmetric matrix $\Phi \in \mathbb{R}^{N \times N}$ of the form $\Phi = -\Delta + W$, where Δ is the discrete Laplacian, and W a random “potential”. The precise definition of Φ depends on the BC:

$$\begin{aligned}
 \Phi_{j,k} &= (2 + v_k) \delta_{j,k} - \delta_{j,k+1} - \delta_{j,k-1} && \text{(fixed BC),} \\
 \Phi_{j,k} &= (2 + v_k) \delta_{j,k} - \delta_{j,k+1} - \delta_{j,k-1} - \delta_{j,1} \delta_{k,N} - \delta_{j,N} \delta_{k,1} && \text{(periodic BC),}
 \end{aligned}$$

for $1 \leq j, k \leq N$.

The dynamics. The generator of the hamiltonian part of the dynamics is written as

$$A = A_{har} + \lambda' A_{anh}$$

with

$$A_{har} = \sum_{k=1}^N (\partial_{p_k} H_{har} \cdot \partial_{q_k} - \partial_{q_k} H_{har} \cdot \partial_{p_k}) = \langle p, \nabla_q \rangle - \langle \Phi q, \nabla_p \rangle$$

and

$$A_{anh} = - \sum_{k=1}^N \partial_{q_k} H_{anh} \cdot \partial_{p_k} = -(\partial_x U(q_k) + \partial_x V(q_k - q_{k-1}) - \partial_x V(q_{k+1} - q_k)) \cdot \partial_{p_k}.$$

Here, for $x = (x_1, \dots, x_N) \in \mathbb{R}^N$, $\nabla_x = (\partial_{x_1}, \dots, \partial_{x_N})$. The generator of the noise is defined to be

$$\lambda Su = \lambda \sum_{k=1}^N (u(\dots, -p_k, \dots) - u(\dots, p_k, \dots)),$$

with $\lambda \geq \lambda'$. The generator of the full dynamics is given by

$$L = A + \lambda S.$$

We denote by $X_{(\lambda, \lambda')}^t(x)$, or simply by $X^t(x)$, the value of the Markov process generated by L at time $t \geq 0$, starting from $x = (q, p) \in \mathbb{R}^{2N}$.

Expectations. Three different expectations will be considered. We define

- μ_T : the expectation with respect to the Gibbs measure at temperature T ,
- E : the expectation with respect to the realizations of the noise,
- E_v : the expectation with respect to the realizations of the pinnings.

In Sect. 5, it will sometimes be useful to specify the dependence of the Gibbs measure on the system size N ; we then will write it $\mu_T^{(N)}$.

The Gibbs measure μ_T is explicitly given by

$$\mu_T(u) = \frac{1}{Z_T} \int_{\mathbb{R}^{2N}} u(x) e^{-H(x)/T} dx, \quad u : \mathbb{R}^{2N} \rightarrow \mathbb{R},$$

where Z_T is a normalizing factor such that μ_T is a probability measure on \mathbb{R}^{2N} . We will need some properties of this measure. Let us write

$$Z_T^{-1} e^{-H(x)/T} = \rho'(p_1) \dots \rho'(p_N) \cdot \rho''(q),$$

with $\rho'(p_k) = e^{-p_k^2/2T} / \sqrt{2\pi T}$ for $1 \leq k \leq N$.

When $\lambda' = 0$, the density ρ'' is Gaussian:

$$\rho''(q) = (2\pi T)^{-N/2} \cdot (\det \Phi)^{1/2} \cdot e^{-\langle q, \Phi q \rangle / 2T}.$$

Since $\nu_k \geq \nu_- > 0$, it follows from Lemma 1.1 in [9] that $|(\Phi^{-1})_{i,j}| \leq C e^{-c|j-i|}$, for some constants $C < +\infty$ and $c > 0$ independent of N . This implies in particular the decay of correlations

$$\mu_T(q_i q_j) = T (\Phi^{-1})_{i,j} \leq C T e^{-c|j-i|}.$$

When $\lambda' > 0$, the density ρ'' is not Gaussian anymore. We here impose the extra assumption that ν_- is large enough. In that case, our hypotheses ensure that the conclusions of Theorem 3.1 in [7] hold: there exist constants $C < +\infty$ and $c > 0$ such that, for every $f, g \in C_{temp}^\infty(\mathbb{R}^N)$ satisfying $\mu_T(f) = \mu_T(g) = 0$,

$$|\mu_T(f \cdot g)| \leq C e^{-c d(S(f), S(g))} \left(\mu_T((\nabla_q f, \nabla_q f)) \cdot \mu_T((\nabla_q g, \nabla_q g)) \right)^{1/2}. \tag{2.1}$$

Here, $S(u)$ is the support of the function u , defined as the smallest set of integers such that u can be written as a function of the variables x_l for $l \in S(u)$, whereas $d(S(f), S(g))$ is the smallest distance between any integer in $S(f)$ and any integer in $S(g)$. Using that $\mu_T(q_k) = 0$ for $1 \leq k \leq N$, it is checked from (2.1) that every function $u \in C_{temp}^\infty(\mathbb{R}^N)$ with given support independent of N is such that $\|u\|_{L^1(\mu_T)}$ is bounded uniformly in N .

The current. The local energy e_k of atom k is defined as

$$e_k = e_{k,har} + \lambda' e_{k,anh}$$

with

$$e_{k,har} = \frac{p_k^2}{2} + \nu_k \frac{q_k^2}{2} + \frac{1}{4} (q_k - q_{k-1})^2 + \frac{1}{4} (q_{k+1} - q_k)^2 \quad \text{for } 2 \leq k \leq N - 1,$$

and

$$e_{k,anh} = U(q_k) + \frac{V(q_k - q_{k-1})}{2} + \frac{V(q_{k+1} - q_k)}{2} \quad \text{for } 2 \leq k \leq N - 1.$$

For periodic B.C., these expressions are still valid when $k = 1$ or $k = N$. For fixed B.C. instead, all the terms involving the differences $(q_0 - q_1)$ or $(q_{N+1} - q_N)$ in the previous expressions have to be multiplied by 2. These definitions ensure that the total energy H is the sum of the local energies.

The definition of the dynamics implies that

$$de_k = (j_{k-1} - j_k) dt$$

for local currents

$$j_k = j_{k,har} + \lambda' j_{k,anh}$$

defined as follows for $0 \leq k \leq N$. First, for $1 \leq k \leq N - 1$,

$$\begin{aligned} j_{k,har} &= \frac{1}{2}(p_k + p_{k+1})(q_k - q_{k+1}) \quad \text{and} \\ j_{k,anh} &= \frac{1}{2}(p_k + p_{k+1}) \partial_x V(q_k - q_{k+1}). \end{aligned} \tag{2.2}$$

Next, $j_{0,1} = j_{N,N+1} = 0$ for fixed B.C. Finally, j_0 and j_N are still given by (2.2) for periodic B.C., with the conventions $p_0 = p_N$ and $p_{N+1} = p_1$. The total current and the rescaled total current are then defined by

$$J_N = J_{N,har} + \lambda' J_{N,anh} = \sum_{k=1}^N j_{k,har} + \lambda' \sum_{k=1}^N j_{k,anh} \tag{2.3}$$

$$\mathcal{J}_N = \mathcal{J}_{N,har} + \lambda' \mathcal{J}_{N,anh} = \frac{J_{N,har}}{\sqrt{N}} + \lambda' \frac{J_{N,anh}}{\sqrt{N}}. \tag{2.4}$$

2.2 Results

For a given realization of the pinning, the (Green–Kubo) conductivity $\kappa = \kappa(\lambda, \lambda')$ of the chain is defined as

$$\begin{aligned} \kappa(\lambda, \lambda') &= \frac{1}{T^2} \lim_{t \rightarrow \infty} \lim_{N \rightarrow \infty} \kappa_{t,N}(\lambda, \lambda') \\ &= \frac{1}{T^2} \lim_{t \rightarrow \infty} \lim_{N \rightarrow \infty} \mu_T \mathbf{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X_{(\lambda, \lambda')}^s ds \right)^2 \end{aligned} \tag{2.5}$$

if this limit exists. The choice of the boundary conditions is expected to play no role in this formula since the volume size N is sent to infinity for fixed time. The disorder averaged conductivity is defined by replacing $\mu_T \mathbf{E}$ by $\mathbf{E}_v \mu_T \mathbf{E}$ in (2.5). By ergodicity, the conductivity and the disorder averaged conductivity are expected to coincide for almost all realization of the pinning (see [5]). The dependence of $\kappa(\lambda, \lambda')$ on the temperature T will not be analysed in this work, so that we can consider T as a fixed given parameter.

We first obtain an upper bound on the disorder averaged conductivity.

Theorem 1 *Let $0 \leq \lambda' \leq \lambda$. With the assumptions introduced up to here, if v_- is large enough, and for fixed boundary conditions,*

$$\frac{1}{T^2} \limsup_{t \rightarrow \infty} \limsup_{N \rightarrow \infty} \mathbf{E}_v \mu_T \mathbf{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X_{(\lambda, \lambda')}^s \, ds \right)^2 = \mathcal{O}(\lambda) \quad \text{as } \lambda \rightarrow 0. \tag{2.6}$$

Remarks 1. When $\lambda = 0$, the proof (see Sect. 3) actually shows that

$$\frac{1}{T^2} \limsup_{N \rightarrow \infty} \mathbf{E}_v \mu_T \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X_{(0,0)}^s \, ds \right)^2 = \mathcal{O}(t^{-1}) \quad \text{as } t \rightarrow \infty.$$

This bound had apparently never been published before. It says that the unperturbed chain behaves like a perfect insulator: the current integrated over arbitrarily long times remains bounded in $L^2(\mathbf{E}_v \mu_T)$.

2. The proof (see Sect. 3) shares some common features with a method used in [18] to obtain a weak coupling limit for noisy hamiltonian systems. In our case, we may indeed see the eigenmodes of the unperturbed system as weakly coupled by the noise and the anharmonic potentials.
3. The choice of fixed boundary conditions just turns out to be more convenient for technical reasons (see Sect. 4).
4. The hypothesis that v_- is large enough is only used to ensure the exponential decay of correlations of the Gibbs measure when $\lambda' > 0$.

Next, in the absence of anharmonicity ($\lambda' = 0$), results become more refined.

Theorem 2 *Let $\lambda > 0$, let $\lambda' = 0$, and let us assume that hypotheses introduced up to here hold. For almost all realizations of the pinnings, the Green–Kubo conductivity (2.5) of the chain is well defined, and in fact*

$$\kappa(\lambda, 0) = \frac{1}{T^2} \lim_{t \rightarrow \infty} \lim_{N \rightarrow \infty} \mathbf{E}_v \mu_T \mathbf{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X_{(\lambda, 0)}^s \, ds \right)^2, \tag{2.7}$$

this last limit being independent of the choice of boundary conditions (fixed or periodic). Moreover, there exists a constant $c > 0$ such that, for every $\lambda \in]0, 1[$,

$$c\lambda \leq \kappa(\lambda, 0) \leq c^{-1}\lambda. \tag{2.8}$$

The rest of this article is devoted to the proof of these theorems, which is constructed as follows.

Proof of Theorems 1 and 2 The upper bound (2.6) is derived in Sect. 3, assuming that Lemma 1 holds. This lemma is stated and shown in Sect. 4; it encapsulates the

informations we need about the localization of the eigenmodes of the unperturbed system ($\lambda = \lambda' = 0$). The existence of $\kappa(\lambda, 0)$ for almost every realization of the pinnings, together with (2.7), are shown in Sect. 5. Finally, a lower bound on the conductivity when $\lambda' = 0$ is obtained in Sect. 6. This shows (2.8). \square

2.3 Heuristic comments

We would like to give here some intuition on the conductivity of disordered harmonic chains perturbed by a weak noise only, so with $\lambda > 0$ small and $\lambda' = 0$. We will develop in a more probabilistic way some ideas from [12]. Our results cover the case where the pinning parameters ν_k are bounded from below by a positive constant, but it could be obviously desirable to understand the unpinned chain as well, in which case randomness has to be putted on the value of the masses. We handle here both cases.

Let us first assume that $\nu_k \geq c$ for some $c > 0$, and let us consider a typical realization of the pinnings. In the absence of noise ($\lambda = 0$), the dynamics of the chain is actually equivalent to that of N independent one-dimensional harmonic oscillators, called eigenmodes (see Sect. 4.1 and formulas (4.5–4.6) in particular). Since the chain is pinned at each site, the eigenfrequencies of these modes are uniformly bounded away from zero. As a result, all modes are expected to be exponentially localized. We can thus naively think that, to each particle, is associated a mode localized near the equilibrium position of this particle.

When the noise is turned on ($\lambda > 0$), energy starts being exchanged between near modes. Let us assume that, initially, energy is distributed uniformly between all the modes, except around the origin, where some more energy is added. We expect this extra amount of energy to diffuse with time, with a variance proportional to $\kappa(0, \lambda) \cdot t$ at time t . Since flips of velocity occur at random times and with rate λ , we could compare the location of this extra energy at time t to the position of a standard random walk after $n = \lambda t$ steps. Therefore, denoting by δ_k the increments of this walk, we find that

$$\kappa(\lambda, 0) \sim \left\langle \left(\frac{1}{\sqrt{t}} \sum_{k=1}^n \delta_k \right)^2 \right\rangle \sim \lambda.$$

This intuitive picture will only be partially justified, as explained in the remark after the proof of Theorem 1 in Sect. 3.

Let us now consider the unpinned chain. So we put $\nu_k = 0$ and we change p_k^2 by p_k^2/m_k in the Hamiltonian, where the masses m_k are i.i.d. positive random variables. We consider a typical realization of the masses. In contrast with the pinned chain, the eigenfrequencies of the modes are now distributed in an interval of the form $[0, c]$, for some $c > 0$. This has an important consequence on the localization of the modes. It is indeed expected that the localization length l of a mode and its eigenfrequency ω are related through the formula $l \sim 1/\omega^2$.

Here again, the noise induces exchange of energy between modes, and we still would like to compare $\kappa(\lambda, 0) \cdot t$ with the variance of a centered random walk with increments δ_k . However, due to the unlocalized low modes, δ_k can now take larger

values than in the pinned case. Assuming that the eigenfrequencies are uniformly distributed in $[0, c]$, we guess that, for large a ,

$$P(|\delta_k| \geq a) \sim P(1/\omega^2 \geq a) \sim 1/\sqrt{a}.$$

This however neglects a fact. Since energy does not travel faster than ballistically, and since successive flips of the velocity are spaced by time intervals of order $1/\lambda$, it is reasonable to introduce the cut-off $P(|\delta_k| > 1/\lambda) = 0$. With this distribution for $|\delta_k|$, and with $n = \lambda t$, we now find

$$\kappa(\lambda, 0) \sim \left\langle \left(\frac{1}{\sqrt{t}} \sum_{k=1}^n \delta_k \right)^2 \right\rangle \sim \lambda^{-1/2}.$$

This scaling is numerically observed in [12]. The arguments leading to this conclusion are very approximative however, and it should be desirable to analyse this case rigorously as well.

3 Upper bound on the conductivity

We here proceed to the proof of Theorem 1. We assume that Lemma 1 in Sect. 4 holds: there exists a sequence $(u_N)_{N \geq 1} \subset L^2(\mathbb{E}_v \mu_T)$ such that $-A_{har} u_N = \mathcal{J}_{N,har}$, and that $(u_N)_{N \geq 1}$ and $(A_{anh} u_N)_{N \geq 1}$ are both bounded sequences in $L^2(\mathbb{E}_v \mu_T)$. Moreover u_N is of the form $u_N(q, p) = \langle q, \alpha_N q \rangle + \langle p, \gamma_N p \rangle + c_N$, where $\alpha_N, \gamma_N \in \mathbb{R}^{N \times N}$ are symmetric matrices, and where $c_N \in \mathbb{R}$.

Proof of (2.6) Let $0 \leq \lambda' \leq \lambda$, and let u_N be the sequence obtained by Lemma 1 in Sect. 4. Before starting, let us observe that, due to the special form of the function u_N , we may write

$$A_{anh} u_N = \sum_{l=1}^N \phi_l(q) p_l, \tag{3.1}$$

with

$$\phi_l(q) = 2 \sum_{k=1}^N \gamma_{k,l} \cdot \left(\partial_x V(q_{k+1} - q_k) - \partial_x V(q_k - q_{k-1}) - \partial_x U(q_k) \right), \tag{3.2}$$

where $(\gamma_{k,l})_{1 \leq k, l \leq N}$ are the entries of γ_N . It follows in particular that

$$A_{anh} u_N = \frac{1}{2} (-S) A_{anh} u_N. \tag{3.3}$$

Now, since $\mathcal{J}_N = \mathcal{J}_{N,har} + \lambda' \mathcal{J}_{N,anh}$, we find using Cauchy–Schwarz inequality that

$$\begin{aligned} \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X^s \, ds \right)^2 &\leq \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,har} \circ X^s \, ds \right)^2 \\ &\quad + (\lambda')^2 \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,anh} \circ X^s \, ds \right)^2 \\ &\quad + 2\lambda' \left(\mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,har} \circ X^s \, ds \right)^2 \right. \\ &\quad \left. \times \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,anh} \circ X^s \, ds \right)^2 \right)^{1/2}. \end{aligned}$$

Since $\mathcal{J}_{N,anh} = \frac{1}{2}(-S)\mathcal{J}_{N,anh}$, a classical bound [15, Appendix 1, Proposition 6.1] furnishes

$$\begin{aligned} \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,anh} \circ X^s \, ds \right)^2 &\leq C \mathbb{E}_v \mu_T (\mathcal{J}_{N,anh} \cdot (-\lambda S)^{-1} \mathcal{J}_{N,anh}) \\ &\leq \frac{C}{2\lambda} \mathbb{E}_v \mu_T (\mathcal{J}_{N,anh}^2) \end{aligned}$$

where $C < +\infty$ is a universal constant. By (2.1), $\mathbb{E}_v \mu_T (\mathcal{J}_{N,anh}^2)$ is uniformly bounded in N . Therefore

$$\limsup_{t \rightarrow \infty} \limsup_{N \rightarrow \infty} \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,anh} \circ X^s \, ds \right)^2 = \mathcal{O}(\lambda^{-1}).$$

It suffices thus to establish that

$$\limsup_{t \rightarrow \infty} \limsup_{N \rightarrow \infty} \mathbb{E}_v \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,har} \circ X^s \, ds \right)^2 = \mathcal{O}(\lambda).$$

We write

$$\begin{aligned} \mathcal{J}_{N,har} &= -A_{har} u_N = -L u_N + \lambda' A_{anh} u_N + \lambda S u_N \\ &= -L u_N + \lambda S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N, \end{aligned}$$

where the second equality is obtained by means of (3.3). Therefore

$$\begin{aligned} \frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_{N,har} \circ X^s \, ds &= \frac{-1}{\sqrt{t}} \int_0^t Lu_N \circ X^s \, ds \\ &\quad + \frac{\lambda}{\sqrt{t}} \int_0^t S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \circ X^s \, ds \\ &= \frac{1}{\sqrt{t}} \mathcal{M}_t - \frac{u \circ X^t - u}{\sqrt{t}} \\ &\quad + \frac{\lambda}{\sqrt{t}} \int_0^t S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \circ X^s \, ds, \end{aligned} \tag{3.4}$$

where \mathcal{M}_t is a martingale given by

$$\mathcal{M}_t = \int_0^t \sum_{j=1}^N S_j u_N \circ X_s \, (dN_s^j - \lambda ds),$$

with N_s^j the Poisson process that flips the momentum of particle j .

It now suffices to establish that the three terms in the right hand side of (3.4) are $\mathcal{O}(\lambda)$ in $L^2(\mathbb{E}_v \mathbb{E}_T)$. Let us first show that $\mu_T(u_N \cdot (-S)u_N) \leq 4\|u_N\|_{L^2(\mu_T)}^2$. Writing

$$u_N = u_N^{p,p,0} + u_N^{p,p,1} + u_N^{q,q} + c_N$$

with

$$u_N^{p,p,0} = \sum_{i \neq j} \gamma_{i,j} p_i p_j, \quad u_N^{p,p,1} = \sum_i \gamma_{i,i} p_i^2, \quad u_N^{q,q} = \langle q, \alpha_N q \rangle,$$

we get indeed

$$\mu_T(u_N \cdot (-S)u_N) = \mu_T \left(u_N \cdot (-S)u_N^{p,p,0} \right) = 4 \mu_T \left(u_N^{p,p,0} \cdot u_N^{p,p,0} \right)$$

and

$$\begin{aligned} \mu_T(u_N \cdot u_N) &= \mu_T(u_N^{p,p,0} \cdot u_N^{p,p,0}) + \mu_T((u_N^{p,p,1} + u_N^{q,q} + c_N)^2) \\ &\quad + 2 \mu_T((u_N^{p,p,1} + u_N^{q,q} + c_N) \cdot u_N^{p,p,0}). \end{aligned}$$

The claim follows since $\mu_T((u_N^{p,p,1} + u_N^{q,q} + c_N) \cdot u_N^{p,p,0}) = 0$.

So first,

$$\mu_T \mathbf{E} \left(\frac{1}{\sqrt{t}} \mathcal{M}_t \right)^2 = 2\lambda \mu_T (u_N \cdot (-S)u_N) \leq 8\lambda \|u_N\|_{L^2(\mu_T)}^2.$$

Next,

$$\mu_T \mathbf{E} \left(\frac{u \circ X_t - u}{\sqrt{t}} \right)^2 \leq \frac{2}{t} \|u_N\|_{L^2(\mu_T)}^2.$$

Finally, by a classical bound ([15], Appendix 1, Proposition 6.1),

$$\begin{aligned} & \mu_T \mathbf{E} \left(\frac{\lambda}{\sqrt{t}} \int_0^t S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \circ X_s \, ds \right)^2 \\ & \leq C \lambda^2 \mu_T \left(S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \cdot (-\lambda S)^{-1} S \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \right) \\ & = C \lambda \mu_T \left(\left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \cdot (-S) \left(Id - \frac{\lambda'}{2\lambda} A_{anh} \right) u_N \right) \\ & = C \lambda \left(\mu_T (u_N \cdot (-S)u_N) + \frac{1}{2} \left(\frac{\lambda'}{\lambda} \right)^2 \|A_{anh} u_N\|_{L^2(\mu_T)}^2 \right) \\ & \leq C \lambda \left(\|u_N\|_{L^2(\mu_T)}^2 + \|A_{anh} u_N\|_{L^2(\mu_T)}^2 \right) \end{aligned}$$

where (3.3) and

$$\mu_T (u_N, A_{anh} u_N) = \mu_T \left((\langle q, \alpha_N q \rangle + \langle p, \gamma_N p \rangle + c_N) \cdot \sum_{l=1}^N \phi_l(q) p_l \right) = 0$$

have been used to get the second equality. Taking the expectation over the pinnings, the proof is completed since $(u_N)_N$ and $(A_{anh} u_N)_N$ are bounded sequences in $L^2(\mathbf{E}_\nu \mu_T)$. \square

Remark When $\lambda' = 0$, formula (3.4) becomes

$$\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X^s \, ds = \frac{1}{\sqrt{t}} \mathcal{M}_t - \frac{u_N \circ X^t - u_N}{\sqrt{t}} + \frac{\lambda}{\sqrt{t}} \int_0^t S u_N \circ X^s \, ds. \tag{3.5}$$

Now, since $S u_N = -4 \sum_{1 \leq k \neq l \leq N} \gamma_{k,l} p_k p_l$, it is computed that

$$\int_0^t \mathcal{J}_N \circ X_{t-s} \, ds = - \int_0^t \mathcal{J}_N \circ X_s \, ds \quad \text{and} \quad \int_0^t S u_N \circ X_{t-s} \, ds = \int_0^t S u_N \circ X_s \, ds.$$

The measure on the paths being invariant under time reversal, it thus holds that

$$\mu_T \mathbb{E} \left(\int_0^t \mathcal{J}_N \circ X_s \, ds \cdot \int_0^t Su_N \circ X_s \, ds \right) = 0.$$

We therefore deduce from (3.5) that

$$\begin{aligned} & \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N(s) \, ds \right)^2 \\ &= \mu_T \mathbb{E} \left(\frac{1}{\sqrt{t}} \mathcal{M}_t \right)^2 - \mu_T \mathbb{E} \left(\frac{\lambda}{\sqrt{t}} \int_0^t Su_N \circ X_s \, ds \right)^2 + r(t) \end{aligned}$$

where $r(t)$ is quantity that vanishes in the limit $t \rightarrow \infty$. We see thus that our proof does not completely justify the heuristic developed in Sect. 2.3, due to the second term in the right hand side of this last equation. As explained after the statement of Lemma 1 below, the sequence u_N should not be unique. It could be that a good choice of sequence u_N makes this second term of order $\mathcal{O}(\lambda^2)$.

4 Poisson equation for the unperturbed dynamics

In this section, we state and prove the following lemma. Fixed BC are assumed for the whole section.

Lemma 1 *Let $\lambda' \geq 0$, and assume fixed boundary conditions. For every $N \geq 1$, and for almost every realization of the pinning, there exist a function u_N of the form*

$$u_N(q, p) = \langle q, \alpha_N q \rangle + \langle p, \gamma_N p \rangle + c_N,$$

where $\alpha_N, \gamma_N \in \mathbb{R}^{N \times N}$ are symmetric matrices and where $c_N \in \mathbb{R}$, such that

$$-A_{har} u_N = \mathcal{J}_{N,har}. \tag{4.1}$$

Moreover, the functions u_N can be taken so that

$$(u_N)_{N \geq 1} \text{ and } (A_{anh} u_N)_{N \geq 1} \text{ are bounded sequences in } L^2(\mathbb{E}_v \mu_T).$$

Remarks 1. The parameter λ' only plays a role through the definition of the measure μ_T .

2. For a given value of N and for almost every realization of the pinning, the unperturbed dynamics is integrable, meaning here that it can be decomposed into N ergodic components, each of them corresponding to the motion of a single one-dimensional harmonic oscillator (see Sects. 4.1 and (4.5–4.6) in particular). This

has two implications. First, since (4.1) admits a solution, we conclude that the current \mathcal{J}_N is of mean zero with respect to the microcanonical measures of each ergodic component of the dynamics. Next, the solution u_N is not unique since every function f constant on the ergodic components of the dynamics satisfies $-A_{har} f = 0$.

Proof of Lemma 1 To simplify notations, we will generally not write the dependence on N explicitly. The proof is made of several steps. □

4.1 Identifying $(u_N)_{N \geq 1}$: eigenmode expansion

Let $z > 0$ and let $1 \leq l, m \leq N$. Let us consider the equation

$$(z - A_{har})v_{l,m,z} = q_l p_m.$$

The solution $v_{l,m,z}$ exists and is unique. It is given by

$$v_{l,m,z}(x) = \int_0^\infty e^{-zs} \left[q_l \circ X_{(0,0)}^s(x) \cdot p_m \circ X_{(0,0)}^s(x) \right] ds. \tag{4.2}$$

We will analyse $v_{l,m,z}$ to obtain the sequence u_N . Although we assumed fixed BC, all the results of this subsection apply for periodic BC as well.

Solutions to Hamilton’s equations. The matrix Φ is a real symmetric positive definite matrix in $\mathbb{R}^{N \times N}$, and there exist thus an orthonormal basis $(\xi^k)_{1 \leq k \leq N}$ of \mathbb{R}^N , and a sequence of positive real numbers $(\omega_k^2)_{1 \leq k \leq N}$, such that

$$\Phi \xi^k = \omega_k^2 \xi^k.$$

It may be checked that

$$\min\{v_j : 1 \leq j \leq N\} \leq \omega_k^2 \leq \max\{v_j : 1 \leq j \leq N\} + 4 \tag{4.3}$$

for $1 \leq k \leq N$. According to Proposition II.1 in [16], for almost all realization of the pinnings, none of the eigenvalue is degenerate:

$$\omega_j \neq \omega_k \text{ if } j \neq k, \quad 1 \leq j, k \leq N. \tag{4.4}$$

In the sequel, we will assume that (4.4) holds.

When $\lambda = \lambda' = 0$, Hamilton’s equations write

$$dq = p dt, \quad dp = -\Phi q dt.$$

For initial conditions (q, p) , the solutions write

$$q(t) = \sum_{k=1}^N \left(\langle q, \xi^k \rangle \cos \omega_k t + \frac{1}{\omega_k} \langle p, \xi^k \rangle \sin \omega_k t \right) \xi^k, \tag{4.5}$$

$$p(t) = \sum_{k=1}^N \left(-\omega_k \langle q, \xi^k \rangle \sin \omega_k t + \langle p, \xi^k \rangle \cos \omega_k t \right) \xi^k. \tag{4.6}$$

An expression for $v_{l,m,z}$. To determine $v_{l,m,z}$, we just need to insert the solutions (4.5–4.6) into the definition (4.2), and then compute the integral, which is a sum of Laplace transforms of sines and cosines:

$$\begin{aligned} v_{l,m,z}(q, p) &= \frac{1}{4} \sum_{k=1}^N \langle l, \xi^k \rangle \langle m, \xi^k \rangle \left(-\langle q, \xi^k \rangle^2 + \frac{1}{\omega_k^2} \langle p, \xi^k \rangle^2 \right) \\ &+ \sum_{1 \leq j \neq k \leq N} \langle l, \xi^j \rangle \langle m, \xi^k \rangle \left(\frac{\omega_k^2}{\omega_j^2 - \omega_k^2} \langle q, \xi^j \rangle \langle q, \xi^k \rangle + \frac{1}{\omega_j^2 - \omega_k^2} \langle p, \xi^j \rangle \langle p, \xi^k \rangle \right) \\ &+ \mathcal{O}(z), \end{aligned} \tag{4.7}$$

where $\langle j, \xi^k \rangle$ denotes the j th component of the vector ξ^k , and where the rest term $\mathcal{O}(z)$ is a polynomial of the form $\langle q, \tilde{\alpha}_z q \rangle + \langle q, \tilde{\beta}_z p \rangle + \langle p, \tilde{\gamma}_z p \rangle$, where $\tilde{\alpha}_z$ and $\tilde{\gamma}_z$ can be taken to be symmetric. We define

$$v_{l,m} = \lim_{z \rightarrow 0} v_{l,m,z}.$$

It is observed that $v_{l,m}$ is of the form $\langle q, \tilde{\alpha} q \rangle + \langle p, \tilde{\gamma} p \rangle$ where $\tilde{\alpha}$ and $\tilde{\gamma}$ can be taken to be symmetric.

Defining the solution u_N . For fixed BC, the total current is given by

$$J_N = \frac{1}{2} (q_1 p_1 - q_N p_N) + \frac{1}{2} \sum_{k=1}^{N-1} (q_k p_{k+1} - q_{k+1} p_k)$$

Setting

$$w_l = v_{l,l-1} - v_{l-1,l} - \mu_T (v_{l,l-1} - v_{l-1,l}) \tag{4.8}$$

for $2 \leq l \leq N$ and

$$w_1 = v_{N,N} - v_{1,1} - \mu_T (v_{N,N} - v_{1,1}), \tag{4.9}$$

we define

$$u_N = \frac{-1}{2\sqrt{N}} \sum_{k=1}^N w_l.$$

The function u_N is of the form $u_N = \langle q, \alpha_N q \rangle + \langle p, \gamma_N p \rangle + c_N$, where α_N and γ_N are symmetric matrices, and where $c_N \in \mathbb{R}$.

Let us show that u_N solves $-A_{anh}u_N = \mathcal{J}_N$. We may assume that $c_N = 0$ without loss of generality. The current \mathcal{J}_N can be written as $\mathcal{J}_N = \langle q, Bp \rangle$. The function u_N has been obtained as the limit as $z \rightarrow 0$ of the function u_z of the form $u_z = \langle q, \alpha_z q \rangle + \langle q, \beta_z p \rangle + \langle p, \gamma_z p \rangle$ which solves $(z - A_{har})u_z = \mathcal{J}_N$, and with α_z and γ_z symmetric matrices. Since

$$(z - A_{har})u_z = \langle q, (z\alpha_z + \beta_z \Phi)q \rangle + \langle q, (z\beta_z - 2(\alpha_z - \Phi\gamma_z))p \rangle + \langle p, (z - \beta_z)p \rangle,$$

it holds that¹

$$z\alpha_z + \frac{1}{2}(\beta_z \Phi + \Phi\beta_z^\dagger) = 0, \quad z\beta_z - 2(\alpha_z - \Phi\gamma_z) = B, \quad z - \frac{1}{2}(\beta_z + \beta_z^\dagger) = 0.$$

We know that $(\alpha_z, \beta_z, \gamma_z) \rightarrow (\alpha, 0, \gamma)$ as $z \rightarrow 0$, with α and γ symmetric, so that $-2(\alpha - \Phi\gamma) = B$. Taking into account that α and γ are symmetric, we deduce that

$$\Phi\gamma - \gamma\Phi = \frac{1}{2}(B - B^\dagger), \quad 2\alpha = 2\Phi\gamma - B. \tag{4.10}$$

It is checked that, if two symmetric matrices α and γ satisfy these relations, then $u_N = \langle q, \alpha q \rangle + \langle p, \gamma p \rangle$ solves the equation $-A_{har}u_N = \mathcal{J}_N$.

4.2 A new expression for w_l

For $1 \leq l \leq N$, the function w_l defined by (4.8) or (4.9) can be written as

$$w_l = \langle q, \alpha(l)q \rangle + \langle p, \gamma(l)p \rangle + c(l),$$

where $\alpha(l)$ and $\gamma(l)$ are symmetric matrices, and where $c(l) \in \mathbb{R}$. A relation similar to (4.10) is satisfied: with the definitions

$$\begin{aligned} (B(l))_{m,n} &= \delta_{l,l-1}(m, n) - \delta_{l-1,l}(m, n) \quad (2 \leq l \leq N) \quad \text{and} \\ (B(1))_{m,n} &= \delta_{N,N}(m, n) - \delta_{1,1}(m, n), \end{aligned}$$

for $1 \leq m, n \leq N$, we write

$$2\alpha(l) = 2\Phi\gamma(l) - B(l), \tag{4.11}$$

¹ Here and in the following M^\dagger denotes the transpose matrix of the matrix M .

for $1 \leq l \leq N$. Therefore the knowledge of the matrices γ implies that of the matrices α .

An expression for the matrices $\gamma(l)$ can be recovered from (4.7) with $z = 0$. We will now work this out in order to obtain a more tractable formula. We show here that, for $2 \leq l \leq N$,

$$\begin{aligned} \gamma_{s,s}(l) &= - \sum_{j=l}^N \sum_{k=1}^N \langle s, \xi^k \rangle^2 \langle j, \xi^k \rangle^2, & 1 \leq s \leq l - 1, \\ \gamma_{s,s}(l) &= \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2, & l \leq s \leq N, \\ \gamma_{s,t}(l) &= \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle \langle t, \xi^k \rangle, & 1 \leq s \neq t \leq N, \\ &= - \sum_{j=l}^N \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle \langle t, \xi^k \rangle, & 1 \leq s \neq t \leq N \end{aligned} \tag{4.12}$$

and

$$\begin{aligned} \gamma_{s,t}(1) &= \frac{1}{4} \sum_{k=1}^N \frac{\langle N, \xi^k \rangle^2}{\omega_k^2} \langle s, \xi^k \rangle \langle t, \xi^k \rangle - \frac{1}{4} \sum_{k=1}^N \frac{\langle 1, \xi^k \rangle^2}{\omega_k^2} \langle s, \xi^k \rangle \langle t, \xi^k \rangle, \\ &1 \leq s, t \leq N. \end{aligned} \tag{4.13}$$

Formula (4.13) is directly derived from (4.7), noting that $\gamma(1)$ is the only symmetric matrix such that $w_1(0, p) = \sum_{s,t} \gamma_{s,t}(1) p_s p_t$. To derive (4.12), we observe that $\gamma(l)$ is the only symmetric matrix such that $w_l(0, p) = \sum_{s,t} \gamma_{s,t}(l) p_s p_t$. Starting from (4.7), we deduce

$$\begin{aligned} w_l(0, p) &= (u_{l,l-1} - u_{l-1,l})(0, p) \\ &= \sum_{1 \leq j \neq k \leq N} \left(\langle l, \xi^j \rangle \langle l - 1, \xi^k \rangle - \langle l - 1, \xi^j \rangle \langle l, \xi^k \rangle \right) \frac{\langle p, \xi^j \rangle \langle p, \xi^k \rangle}{\omega_j^2 - \omega_k^2}. \end{aligned}$$

For fixed BC, the eigenvectors ξ^j satisfy the following relations for $1 \leq j \leq N$:

$$\begin{aligned} \langle \xi^j, 0 \rangle &= \langle \xi^j, N + 1 \rangle = 0 \quad (\text{by definition}), \\ -\langle \xi^j, m - 1 \rangle + (2 + v_m) \langle \xi^j, m \rangle - \langle \xi^j, m + 1 \rangle &= \omega_j^2 \langle \xi^j, m \rangle, \quad 1 \leq m \leq N. \end{aligned}$$

So the following recurrence relation is satisfied:

$$\langle \xi^j, m + 1 \rangle = (2 + v_m - \omega_j^2) \langle \xi^j, m \rangle - \langle \xi^j, m - 1 \rangle, \quad 1 \leq m \leq N. \tag{4.14}$$

Let us first compute $w_2(0, p)$. Using (4.14), it comes

$$\begin{aligned} \langle 2, \xi^j \rangle \langle 1, \xi^k \rangle - \langle 1, \xi^j \rangle \langle 2, \xi^k \rangle &= (2 + \nu_1 - \omega_j^2) \langle 1, \xi^j \rangle \langle 1, \xi^k \rangle \\ &\quad - (2 + \nu_1 - \omega_k^2) \langle 1, \xi^j \rangle \langle 1, \xi^k \rangle \\ &= -(\omega_j^2 - \omega_k^2) \langle 1, \xi^j \rangle \langle 1, \xi^k \rangle. \end{aligned}$$

Therefore

$$\begin{aligned} w_2(0, p) &= - \sum_{1 \leq j \neq k \leq N} \langle 1, \xi^j \rangle \langle 1, \xi^k \rangle \langle p, \xi^j \rangle \langle p, \xi^k \rangle \\ &= - \sum_{1 \leq j, k \leq N} \langle 1, \xi^j \rangle \langle 1, \xi^k \rangle \langle p, \xi^j \rangle \langle p, \xi^k \rangle + \sum_{k=1}^N \langle 1, \xi^k \rangle^2 \langle p, \xi^k \rangle^2 \\ &= -\langle 1, p \rangle^2 + \sum_{k=1}^N \langle 1, \xi^k \rangle^2 \langle p, \xi^k \rangle^2, \end{aligned} \tag{4.15}$$

where the last equality follows from the fact that $(\xi^k)_k$ forms an orthonormal basis.

Let us now compute $w_l(0, p)$ for $2 < l \leq N$. Again by (4.14),

$$\begin{aligned} \langle l, \xi^j \rangle \langle l-1, \xi^k \rangle - \langle l-1, \xi^j \rangle \langle l, \xi^k \rangle &= \left((2 + \nu_{l-1} - \omega_j^2) \langle l-1, \xi^j \rangle - \langle l-2, \xi^j \rangle \right) \langle l-1, \xi^k \rangle \\ &\quad - \langle l-1, \xi^j \rangle \left((2 + \nu_{l-1} - \omega_k^2) \langle l-1, \xi^k \rangle - \langle l-2, \xi^k \rangle \right) \\ &= -(\omega_j^2 - \omega_k^2) \langle l-1, \xi^j \rangle \langle l-1, \xi^k \rangle \\ &\quad + \langle l-1, \xi^j \rangle \langle l-2, \xi^k \rangle - \langle l-2, \xi^j \rangle \langle l-1, \xi^k \rangle. \end{aligned}$$

Therefore

$$\begin{aligned} w_l(0, p) &= - \sum_{1 \leq j \neq k \leq N} \langle l-1, \xi^j \rangle \langle l-1, \xi^k \rangle \langle p, \xi^j \rangle \langle p, \xi^k \rangle + w_{l-1}(0, p) \\ &= -\langle l-1, p \rangle^2 + \sum_{k=1}^N \langle l-1, \xi^k \rangle^2 \langle p, \xi^k \rangle^2 + w_{l-1}(0, p). \end{aligned} \tag{4.16}$$

Combining (4.15) and (4.16), we arrive to an expression valid for $2 \leq l \leq N$:

$$w_l(0, p) = \sum_{j=1}^{l-1} \left(\sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle p, \xi^k \rangle^2 - \langle j, p \rangle^2 \right).$$

Let us now write $\langle j, p \rangle^2 = p_j^2$ and

$$\langle p, \xi^k \rangle^2 = \left(\sum_s p_s \langle s, \xi^k \rangle \right)^2 = \sum_{s,t} p_s p_t \langle s, \xi^k \rangle \langle t, \xi^k \rangle.$$

We obtain

$$\begin{aligned} w_l(0, p) &= \sum_{s,t} p_s p_t \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle \langle t, \xi^k \rangle - \sum_{j=1}^{l-1} p_j^2 \\ &= \sum_{s=1}^{l-1} p_s^2 \left(\sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2 - 1 \right) \\ &\quad + \sum_{s=l}^N p_s^2 \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2 \\ &\quad + \sum_{1 \leq s \neq t \leq N} p_s p_t \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle \langle t, \xi^k \rangle. \end{aligned}$$

In this formula, the coefficients of p_s^2 coincide with $\gamma_{s,s}(l)$ given by (4.12) for $l \leq s \leq N$, and the coefficients of $p_s p_t$ with $s \neq t$ coincide with the first expression of $\gamma_{s,t}(l)$ given by (4.12). To recover the coefficients $\gamma_{s,s}(l)$ for $1 \leq s \leq l - 1$, just use the fact that $(\xi^k)_k$ and $(|k\rangle)_k$ are orthonormal basis:

$$\begin{aligned} \sum_{j=1}^{l-1} \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2 - 1 &= \sum_{k=1}^N \left(1 - \sum_{j=l}^N \langle j, \xi^k \rangle^2 \right) \langle s, \xi^k \rangle^2 - 1 \\ &= \sum_{k=1}^N \langle s | \xi^k \rangle^2 - 1 - \sum_{j=l}^N \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2 \\ &= - \sum_{j=l}^N \sum_{k=1}^N \langle j, \xi^k \rangle^2 \langle s, \xi^k \rangle^2. \end{aligned}$$

The second expression for the coefficients $\gamma_{s,t}(l)$ with $s \neq t$ in (4.12) is obtained by a similar trick.

4.3 Exponential bounds

We show here that there exist constants $C < +\infty$ and $c > 0$ independent of N such that

$$\begin{aligned} \mathbb{E}_v \left(\alpha_{j,k}^2(l) \right) &\leq C \exp \left(-c(|j-l| + |k-l|) \right), \quad \mathbb{E}_v \left(\gamma_{j,k}^2(l) \right) \\ &\leq C \exp \left(-c(|j-l| + |k-l|) \right), \end{aligned} \tag{4.17}$$

for $2 \leq l \leq N$ and for $1 \leq j, k \leq N$. This is still valid for $l = 1$ if $|k-l|$ is replaced by $\min\{|k-1|, |k-N|\}$ and $|j-l|$ by $\min\{|j-1|, |j-N|\}$. Due to (4.11), it suffices to establish these bounds for the matrices γ .

Let us first observe that the almost sure bounds

$$|\gamma_{s,t}(l)| \leq 1 \quad (2 \leq l \leq N), \quad |\gamma_{s,t}(1)| \leq \frac{1}{2 \min\{\omega_k^2 : 1 \leq k \leq N\}}$$

hold for $1 \leq s, t \leq N$. This is directly deduced from (4.12) and (4.13) by taking absolute values inside the sums if needed, using that $(\xi^k)_k$ and $(|k\rangle)_k$ are orthonormal basis, and Cauchy-Schwarz inequality if needed. By (4.3), $\min\{\omega_k^2 : 1 \leq k \leq N\} \geq c > 0$, where c does not depend on N . In particular $\mathbb{E}_v (|\gamma_{s,t}|^p) \leq C_p \mathbb{E}_v |\gamma_{s,t}|$ for every $p \geq 1$, so that we only need to bound $\mathbb{E}_v |\gamma_{s,t}|$.

We now will apply localization results originally derived by Kunz and Souillard [16], but we follow the exposition given by [11]. From (4.12) and (4.13), we see that we are looking for upper bound on the absolute value of sums of the type

$$\sum_k \langle r, \xi^k \rangle^2 \langle t, \xi^k \rangle^2, \quad r < t,$$

and of the type

$$\begin{aligned} \sum_k \langle r, \xi^k \rangle^2 \langle s, \xi^k \rangle \langle t, \xi^k \rangle, \quad \sum_k \langle r, \xi^k \rangle \langle s, \xi^k \rangle^2 \langle t, \xi^k \rangle, \quad \sum_k \langle r, \xi^k \rangle \langle s, \\ \xi^k \rangle \langle t, \xi^k \rangle^2, \quad r < s < t. \end{aligned}$$

Since $|\langle r, \xi^k \rangle| \leq 1$ for $1 \leq r, k \leq N$, all of them can be bounded by

$$\sum_k |\langle r, \xi^k \rangle \langle t, \xi^k \rangle|.$$

By the formula before Lemma 4.3 in [11], and the lines after the proof of this lemma, we may conclude that there exist constants $C < +\infty$ and $c > 0$ independent of N such that

$$\mathbb{E}_v \left(\sum_k |\langle r, \xi^k \rangle \langle t, \xi^k \rangle| \right) \leq C e^{-c(t-r)}.$$

Together with the remarks formulated up to here, this allows to deduce (4.17).

4.4 Concluding the proof of Lemma 1

We write

$$\begin{aligned} \mathbb{E}_v \mu_T(u_N^2) &= \frac{1}{4N} \sum_{m,n} \mathbb{E}_v \mu_T(w_m \cdot w_n) \quad \text{and} \\ \mathbb{E}_v \mu_T((A_{anh} u_N)^2) &= \frac{1}{4N} \sum_{m,n} \mathbb{E}_v \mu_T(A_{anh} w_m \cdot A_{anh} w_n). \end{aligned}$$

We will establish that there exist constants $C < +\infty$ and $c > 0$ such that

$$|\mathbb{E}_v \mu_T(w_m \cdot w_n)| \leq C e^{-c|m-n|} \quad \text{and} \quad |\mathbb{E}_v \mu_T(A_{anh} w_m \cdot A_{anh} w_n)| \leq C e^{-c|m-n|} \tag{4.18}$$

for $1 \leq m, n \leq N$. This will conclude the proof.

Let us fix $1 \leq m, n \leq N$. Let us first consider $|\mathbb{E}_v \mu_T(w_m \cdot w_n)|$. Let us observe that the functions w_l are of zero mean by construction, and so the relation

$$\sum_j \gamma_{j,j}(l) \int p_j^2 d\mu_T + \sum_{j,k} \alpha_{j,k}(l) \int q_j q_k d\mu_T + c(l) = 0 \tag{4.19}$$

holds for $1 \leq l \leq N$. Using this relation, it is computed that

$$\begin{aligned} \mu_T(w_m \cdot w_n) &= \mu_T \left(\left(\sum_{i,j} \alpha_{i,j}(m) q_i q_j + \sum_{i,j} \gamma_{i,j}(m) p_i p_j + c(m) \right) \right. \\ &\quad \left. \left(\sum_{i,j} \alpha_{i,j}(n) q_i q_j + \sum_{i,j} \gamma_{i,j}(n) p_i p_j + c(n) \right) \right) \\ &= \sum_{i,j,k,l} \alpha_{i,j}(m) \alpha_{k,l}(n) \int q_i q_j q_k q_l d\mu_T \\ &\quad + \sum_{i,j,k,l} \alpha_{i,j}(m) \gamma_{k,l}(n) \int q_i q_j p_k p_l d\mu_T \\ &\quad + \sum_{i,j,k,l} \gamma_{i,j}(m) \alpha_{k,l}(n) \int p_i p_j q_k q_l d\mu_T \\ &\quad + \sum_{i,j,k,l} \gamma_{i,j}(m) \gamma_{k,l}(n) \int p_i p_j p_k p_l d\mu_T - c(m)c(n) \\ &= S_1 + S_2 + S_3 + S_4 - c(m)c(n). \end{aligned}$$

Using (4.19) and the fact that $\int p^2 d\mu_T = T$, the sum S_1 is rewritten as

$$\begin{aligned} S_1 &= \sum_{i,j,k,l} \alpha_{i,j}(m)\alpha_{k,l}(n) \int \left(q_i q_j - \int q_i q_j d\mu_T \right) \left(q_k q_l - \int q_k q_l d\mu_T \right) d\mu_T \\ &\quad + \sum_{i,j,k,l} \alpha_{i,j}(m)\alpha_{k,l}(n) \int q_i q_j d\mu_T \int q_k q_l d\mu_T \\ &= \sum_{i,j,k,l} \alpha_{i,j}(m)\alpha_{k,l}(n) \int \left(q_i q_j - \int q_i q_j d\mu_T \right) \left(q_k q_l - \int q_k q_l d\mu_T \right) d\mu_T \\ &\quad + T^2 \sum_{i,j} \gamma_{i,i}(m)\gamma_{j,j}(n) + Tc(m) \sum_i \gamma_{i,i}(n) + Tc(n) \sum_i \gamma_{i,i}(m) + c(m)c(n). \end{aligned}$$

Then, still using (4.19), we get

$$S_2 + S_3 = -Tc(m) \sum_i \gamma_{i,i}(n) - Tc(n) \sum_i \gamma_{i,i}(m) - 2T^2 \sum_{i,j} \gamma_{i,i}(m)\gamma_{j,j}(n).$$

Finally, the terms in the sum S_4 are non zero only when

$$i = j = k = l, \quad i = j, k = l, i \neq k, \quad i = k, j = l, i \neq j, \quad i = l, j = k, i \neq j.$$

Using that $\int p^4 d\mu_T = 3(\int p^2 d\mu_T)^2$ and that $\int p^2 d\mu_T = T$, S_4 is seen to be equal to

$$S_4 = T^2 \sum_{i,j} \left(\gamma_{i,i}(m)\gamma_{j,j}(n) + 2\gamma_{i,j}(m)\gamma_{i,j}(n) \right).$$

Therefore

$$\begin{aligned} \mu_T(w_m \cdot w_n) &= \sum_{i,j,k,l} \alpha_{i,j}(m)\alpha_{k,l}(n) \int \left(q_i q_j - \int q_i q_j d\mu_T \right) \\ &\quad \times \left(q_k q_l - \int q_k q_l d\mu_T \right) d\mu_T + 2T^2 \sum_{i,j} \gamma_{i,j}(m)\gamma_{i,j}(n). \end{aligned}$$

Applying the decorrelation bound (2.1) and the exponential estimate (4.17), the result is obtained.

Let us next consider $|\mathbb{E}_\nu \mu_T(A_{anh} w_m \cdot A_{anh} w_n)|$. We find from (3.1) that

$$\begin{aligned} \mu_T(A_{anh} w_m \cdot A_{anh} w_n) &= \sum_{s,t} \mu_T(\phi_t(q, m) \phi_s(q, n) p_s p_t) \\ &= T \sum_t \mu_T(\phi_t(q, m) \phi_t(q, n)). \end{aligned}$$

Now, it follows from (3.2) that $\phi_t(q, k) = \sum_s \gamma_{s,t}(k) \rho_s(q)$ for $1 \leq k \leq N$. Here $\rho_s(q) = \rho_s(q_{s-1}, q_s, q_{s+1})$ is a function of mean zero since the potentials U and V are symmetric. We write

$$\mu_T(A_{anh} w_m \cdot A_{anh} w_n) = \sum_t \sum_{s,s'} \gamma_{s,t}(m) \gamma_{s',t}(n) \mu_T(\rho_s \cdot \rho_{s'}).$$

Applying the decorrelation bound (2.1) and the exponential estimate (4.17) yield the result. □

5 Convergence results

In this section we show the convergence result (2.7). We assume thus $\lambda > 0$ and $\lambda' = 0$.

We start with some definitions (see [5] for details). The dynamics defined in Sect. 2 can also be defined for a set of particles indexed in \mathbb{Z} instead of \mathbb{Z}_N . Points on the phase space are written $x = (q, p)$, with $q = (q_k)_{k \in \mathbb{Z}}$ and $p = (p_k)_{k \in \mathbb{Z}}$. Let us denote by \mathcal{L} the generator of this infinite-dimensional dynamics. We remember here that $\mu_T^{(N)}$ represents the Gibbs measure of a system of size N ; we denote by $\mu_T^{(\infty)}$ the Gibbs measure of the infinite system (the dependence on the size will still be dropped in the cases where it is irrelevant). We extend the definition (2.2) of local currents j_k to all $k \in \mathbb{Z}$ ($j_k = j_{k,har}$ since $\lambda' = 0$). If $u = u(x, v)$, with $v = (v_k)_{k \in \mathbb{Z}}$ a sequence of pinnings, and if $k \in \mathbb{Z}$, we write $\tau_k u(x, v) = u(\tau_k x, \tau_k v)$, where

$$(\tau_k q)_j = q_{k+j}, \quad (\tau_k p)_j = p_{k+j}, \quad (\tau_k v)_j = v_{k+j}.$$

Finally, we denote by $\langle\langle \cdot, \cdot \rangle\rangle$ the inner-product defined, for local bounded functions u and v , by

$$\langle\langle u, v \rangle\rangle = \sum_{k \in \mathbb{Z}} E_v(\mu_T^{(\infty)}(u \cdot \tau_k v^*) - \mu_T^{(\infty)}(u) \mu_T^{(\infty)}(v))$$

where v^* is the complex conjugate of v , and by \mathcal{H} the corresponding Hilbert space, obtained by completion of the bounded local functions.

We start with two lemmas. We have no reason to think that Lemma 2 still holds if an anharmonic potential is added, and this is the main reason why we here restrict ourselves to harmonic interactions.

Lemma 2 *There exists a constant $C < +\infty$ such that, for any realization of the pinnings, for the finite dimensional dynamics with free or fixed B.C., or for the infinite dynamics, for any $k \geq 1$ and for any $l \in \mathbb{Z}_N$ (resp. $k \in \mathbb{Z}$ for the infinite dynamics),*

$$\|L^k j_l\|_{L^2(\mu_T)} \leq C^k \quad (\text{resp. } \|\mathcal{L}^k j_l\|_{L^2(\mu_T)} \leq C^k).$$

Proof Let us consider the infinite dimensional dynamics ; other cases are similar. We can take $l = 0$ without loss of generality. The function j_0 is of the form $j_0 = \langle q, \alpha q \rangle + \langle q, \beta p \rangle + \langle p, \gamma p \rangle$, with $\alpha = \gamma = 0$ and β defined by

$$\beta_{i,j} = \frac{1}{2}(\delta_{0,0}(i, j) - \delta_{(1,1)}(i, j) + \delta_{0,1}(i, j) - \delta_{1,0}(i, j)).$$

Now, if u is any function of the type $u = \langle q, \alpha q \rangle + \langle q, \beta p \rangle + \langle p, \gamma p \rangle$, then $\mathcal{L}u = \langle q, \alpha' q \rangle + \langle q, \beta' p \rangle + \langle p, \gamma' p \rangle$ with

$$(\alpha', \beta', \gamma') = \left(-\frac{\beta\Phi + \Phi\beta^\dagger}{2}, \alpha - 2\Phi\gamma - 2\lambda\beta, \frac{\beta + \beta^\dagger}{2} - 4\lambda\tilde{\gamma} \right),$$

where $\tilde{\gamma}$ is such that $(\tilde{\gamma})_{i,i} = 0$ and $(\tilde{\gamma})_{i,j} = \gamma_{i,j}$ for $i \neq j$. Thus

$$\mathcal{L}^k j_0 = \langle q, \alpha_{(k)} q \rangle + \langle q, \beta_{(k)} p \rangle + \langle p, \gamma_{(k)} p \rangle,$$

and there exists a constant $C < +\infty$ such that $\zeta_{i,j} = 0$ whenever $|i| \geq Ck$ or $|j| \geq Ck$ and such that $|\zeta_{i,j}| \leq C^k$ otherwise, with ζ one of the three matrices $\alpha_{(k)}$, $\beta_{(k)}$ or $\gamma_{(k)}$. The claim is obtained by expressing $\|\mathcal{L}^k j_l\|_{L^2(\mu_T)}$ in terms of the matrices $\alpha_{(k)}$, $\beta_{(k)}$ and $\gamma_{(k)}$. □

Explicit representation for the matrix Φ^{-1} in Lemma 1.1. in [9] allows to deduce the following lemma.

Lemma 3 *Let f and g be two polynomials of the type $\langle q, \alpha q \rangle + \langle p, \beta p \rangle + \langle p, \gamma p \rangle$, and assume that there exists $n \in \mathbb{N}$ such that $\alpha_{i,j} = \beta_{i,j} = \gamma_{i,j} = 0$ whenever $|i| > n$ or $|j| > n$. Then there exists $c > 0$ such that, for fixed or periodic B.C.,*

$$|\mu_T^{(N)}(f \cdot g^*) - \mu_T^{(\infty)}(f \cdot g^*)| = \mathcal{O}(e^{-cN}) \text{ as } N \rightarrow \infty.$$

Let then $\mathbb{D} = \{z \in \mathbb{C} : \Re z > 0\}$. For every $z \in \mathbb{D}$, let u_z be the unique solution to the resolvent equation in \mathcal{H}

$$(z - \mathcal{L})u_z = j_0. \tag{5.1}$$

We know from Theorem 1 in [5]², and from its proof, that

$$\lim_{z \rightarrow 0} \ll u_z, j_0 \gg \text{ exists and is finite} \tag{5.2}$$

and that

$$\lim_{z \rightarrow 0} z \ll u_z, u_z \gg = 0. \tag{5.3}$$

² The model studied there is not exactly the same. The proof of the properties we mention here can be however readily adapted.

For $z \in \mathbb{D}$ and $N \geq 3$, let $u_{k,z,N}$ be the unique solution to the equation

$$(z - L)u_{k,z,N} = j_k. \tag{5.4}$$

so that

$$u_{z,N} := \frac{1}{\sqrt{N}} \sum_k u_{k,z,N} \quad \text{solves} \quad (z - L)u_{z,N} = \mathcal{J}_N. \tag{5.5}$$

Lemma 4 *For fixed or free boundary conditions and for almost all realizations of the pinnings,*

$$\begin{aligned} \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} \mu_T(u_{z,N} \cdot \mathcal{J}_N) &= \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} \mathbf{E}_v \mu_T(u_{z,N} \cdot \mathcal{J}_N) = \lim_{z \rightarrow 0} \ll u_z, j_0 \gg, \\ \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} z \mu_T(u_{z,N} \cdot u_{z,N}) &= \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} z \mathbf{E}_v \mu_T(u_{z,N} \cdot u_{z,N}) = 0. \end{aligned}$$

Proof By (5.2) and (5.3), it suffices to establish separately that, for every $z \in \mathbb{D}$, and for almost every realization of the pinnings,

$$\begin{aligned} \lim_{N \rightarrow \infty} \mu_T(u_{z,N} \cdot \mathcal{J}_N) &= \ll u_z, j_0 \gg, & \lim_{N \rightarrow \infty} \mathbf{E}_v \mu_T(u_{z,N} \cdot \mathcal{J}_N) &= \ll u_z, j_0 \gg, \\ \lim_{N \rightarrow \infty} z \mu_T(u_{z,N} \cdot u_{z,N}) &= z \ll u_z, u_z \gg, \\ \lim_{N \rightarrow \infty} z \mathbf{E}_v \mu_T(u_{z,N} \cdot u_{z,N}) &= z \ll u_z, u_z \gg. \end{aligned}$$

The proof of these four relations is in fact very similar, and we will focus on the first one. We proceed in two steps: we first show the result for $|z|$ large enough, and then extend it to all $z \in \mathbb{D}$.

First step. Here we fix $z \in \mathbb{D}$ with $|z|$ large enough. We first assume periodic boundary conditions. The function u_z solving (5.1) may be given by

$$u_z = \sum_{k \geq 0} z^{-(k+1)} \mathcal{L}^k j_0,$$

this series converging in virtue of Lemma 2 for $|z|$ large enough. Let now $n \geq 1$. We compute

$$\begin{aligned} \ll j_0, u_z \gg &= \sum_{k=0}^n z^{-(k+1)} \sum_{l \in \mathbb{Z}} \mathbf{E}_v \mu_T^{(\infty)}(j_l \cdot L^k j_0) \\ &+ \sum_{k=n+1}^{\infty} z^{-(k+1)} \sum_{l \in \mathbb{Z}} \mathbf{E}_v \mu_T^{(\infty)}(j_l \cdot L^k j_0). \end{aligned} \tag{5.6}$$

For every given k , the sum over l is actually a sum over Ck non-zero terms only, for some $C < +\infty$. From this fact and from Lemma 2, it is concluded that the second

sum in the right hand side of (5.6) converges to 0 as $n \rightarrow \infty$. Similarly we write

$$\begin{aligned} \mu_T^{(N)}(\mathcal{J}_N \cdot u_{z,N}) &= \frac{1}{N} \sum_{s,t} \sum_{k=0}^n z^{-(k+1)} \mu_T^{(N)}(j_s \cdot L^k j_t) \\ &\quad + \frac{1}{N} \sum_{s,t} \sum_{k=0}^n z^{-(k+1)} \mu_T^{(N)}(j_s \cdot L^k j_t). \end{aligned} \tag{5.7}$$

Here as well, the second term in (5.7) is such that

$$\lim_{n \rightarrow \infty} \limsup_{N \rightarrow \infty} \frac{1}{N} \sum_{s,t} \sum_{k=0}^n z^{-(k+1)} \mu_T^{(N)}(j_s \cdot L^k j_t) = 0.$$

To handle the first term in (5.7), let us write

$$F_n(v) = \sum_{t \in \mathbb{Z}_N} \sum_{k=0}^n z^{-(k+1)} \mu_T^{(N)}(j_0 \cdot L^k j_t).$$

Then in fact

$$\frac{1}{N} \sum_{s,t} \sum_{k=0}^n z^{-(k+1)} \mu_T^{(N)}(j_s \cdot L^k j_t) = \frac{1}{N} \sum_s F_n(\tau_s v).$$

The result is obtained by letting $N \rightarrow \infty$, invoking Lemma 3 and the ergodic theorem, and then letting $n \rightarrow \infty$. If we had started with fixed boundary conditions, then, for every fixed n , all the previous formulas remain valid up to some border terms that vanish in the limit $N \rightarrow \infty$ due to the factor $1/N$.

Second step. Denote by $\mathfrak{L}_{N,v}(z)$ and $\mathfrak{L}(z)$ the complex functions defined on \mathbb{D} by

$$\mathfrak{L}_{N,v}(z) = \mu_T^{(N)}(u_{z,N} \cdot \mathcal{J}_N) \quad \text{and} \quad \mathfrak{L}(z) = \ll u_z, j_0 \gg.$$

The first observation is that these functions are well defined and analytic on \mathbb{D} . Moreover, similarly to what is proved in [5], they are uniformly bounded on \mathbb{D} by a constant independent of N and the realization of the pinning v .

Let us fix a realization of the pinnings. The family $\{\mathfrak{L}_{N,v} ; N \geq 1\}$ is a normal family and by Montel’s Theorem we can extract a subsequence $\{\mathfrak{L}_{N_k,v}\}_{k \geq 1}$ such that it converges (uniformly on every compact set of \mathbb{D}) to an analytic function f_v^* .

By the first step we know that $f_v^*(z) = \mathfrak{L}(z)$ for any real $z > z_0$. Thus, since the functions involved are analytic, f_v^* coincides with \mathfrak{L} on \mathbb{D} . It follows that the sequence $\{\mathfrak{L}_{N,v}(z)\}_{N \geq 1}$ converges for any $z \in \mathbb{D}$ to $\mathfrak{L}(z)$. □

Following a classical argument, we can now proceed to the *Proof of (2.7)* For any $z > 0$, it holds that

$$\begin{aligned} \frac{1}{\sqrt{t}} \int_0^t \mathcal{J}_N \circ X^s \, ds &= -\frac{1}{\sqrt{t}} \int_0^t L u_{z,N} \circ X^s \, ds + \frac{z}{\sqrt{t}} \int_0^t u_{z,N} \circ X^s \, ds \\ &= \frac{1}{\sqrt{t}} \mathcal{M}_{z,N,t} - \frac{u_{z,N} \circ X^t - u_{z,N}}{\sqrt{t}} + \frac{z}{\sqrt{t}} \int_0^t u_{z,N} \circ X^s \, ds \end{aligned}$$

Here $\mathcal{M}_{z,N,t}$ is a stationary martingale with variance given by

$$\mu_T \mathbb{E}(\mathcal{M}_{z,N,t}^2) = \mu_T(u_{z,N} \cdot (z - L)u_{z,N}) - z \mu_T(u_{z,N} \cdot u_{z,N}). \tag{5.8}$$

Here the equality $\mu_T(u_{z,N} \cdot A_{har} u_{z,N}) = 0$ has been used. Next

$$\mu_T \mathbb{E} \left(\frac{u_{z,N} \circ X^t - u_{z,N}}{\sqrt{t}} \right)^2 \leq \frac{2}{t} \mu_T(u_{z,N} \cdot u_{z,N})$$

and

$$\mu_T \mathbb{E} \left(\frac{z}{\sqrt{t}} \int_0^t u_{z,N} \circ X^s \, ds \right)^2 \leq z^2 t \mu_T(u_{z,N} \cdot u_{z,N}).$$

Reminding that $\mu_T(u_{z,N} \cdot (z - L)u_{z,N}) = \mu_T(u_{z,N} \cdot \mathcal{J}_N)$, the proof is completed by taking $z = 1/t$ and invoking Lemma 4. □

6 Lower bound in the absence of anharmonicity

We here establish the lower bound in (2.8), and so we assume $\lambda > 0$ and $\lambda' = 0$. We also assume periodic boundary conditions. We use the same method as in [5] (see also [12]). According to Sect. 5, it is enough to establish that there exists a constant $c > 0$ such that, for almost every realization of the pinning, for every $z > 0$ and for every $N \geq 3$,

$$\mu_T(\mathcal{J}_N \cdot (z - L)^{-1} \mathcal{J}_N) \geq c. \tag{6.1}$$

Indeed, by (5.5), $\mu_T(\mathcal{J}_N \cdot (z - L)^{-1} \mathcal{J}_N) = \mu_T(u_{z,N} \cdot (z - L)u_{z,N})$, and, by (5.8), this quantity converges to the right hand side of (2.7).

Proof of (6.1) For periodic B.C., the total current J_N is given by

$$J_N = \frac{1}{2} \sum_{k \in \mathbb{Z}_N} (q_k p_{k+1} - q_{k+1} p_k).$$

To get a lower bound on the conductivity, we use the following variational formula

$$\mu_T \left(J_N (z - L)^{-1} J_N \right) = \sup_f \left\{ 2\mu_T(J_N \cdot f) - \mu_T(f \cdot (z - \lambda S)f) - \mu_T \left(A_{har} f \cdot (z - \lambda S)^{-1} A_{har} f \right) \right\} \tag{6.2}$$

where the supremum is carried over the test functions $f \in C_{temp}^\infty(\mathbb{R}^{2N})$. See [23] for a proof. We take f in the form

$$f = a\langle q, \beta p \rangle \quad \text{with } a \in \mathbb{R} \text{ and } \beta = \Phi M,$$

where M is the antisymmetric matrix such that $M_{i,j} = \delta_{i,j-1} - \delta_{i,j+1}$, with the convention of periodic B.C.: $\delta_{1,N+1} = \delta_{1,1}$ and $\delta_{N,0} = \delta_{N,N}$.

First, we have

$$A_{har} f = a\langle p, \beta p \rangle - a\langle q, \beta \Phi q \rangle = a \sum_{i \neq j} \beta_{i,j} p_i p_j$$

since $\beta \Phi = \Phi M \Phi$ is antisymmetric, and since $\beta_{i,i} = 0$ for $1 \leq i \leq N$. Since $S(p_i p_j) = -4p_i p_j$ for $i \neq j$, we obtain

$$\begin{aligned} \mu_T \left(Af \cdot (z - \lambda S)^{-1} Af \right) &= \frac{1}{z + 4\lambda} \mu_T(A_{har} f \cdot A_{har} f) \\ &= \frac{a^2 T^2}{z + 4\lambda} \sum_{i \neq j} (\beta_{i,j}^2 + \beta_{i,j} \beta_{j,i}) \\ &\leq C \frac{a^2 T^2 N}{z + 4\lambda} \end{aligned} \tag{6.3}$$

for some constant $C < +\infty$. Next, since $S p_k = -2p_k$ for $k \leq N$, there exists some constant $C < +\infty$ such that

$$\begin{aligned} \mu_T(f \cdot (z - \lambda S)f) &= a^2 T^2 (z + 2\lambda) \sum_{i,j} \beta_{i,j} (\Phi^{-1} \beta)_{i,j} \\ &= a^2 T^2 (z + 2\lambda) \text{Tr} \left[\beta^\dagger \Phi^{-1} \beta \right] \\ &\leq C a^2 T^2 (z + 2\lambda) N. \end{aligned} \tag{6.4}$$

Let us finally estimate the term $\mu_T(J_N f)$:

$$\begin{aligned} \mu_T(J_N f) &= \frac{a}{2} \mu_T \left(\sum_{i,j} \beta_{i,j} q_i p_j \cdot \sum_{k \in \mathbb{Z}_N} (q_k p_{k+1} - q_{k+1} p_k) \right) \\ &= \frac{a T^2}{2} \sum_{i,k} (\beta_{i,k+1} \mu_T(q_i q_k) - \beta_{i,k} \mu_T(q_i q_{k+1})) \end{aligned}$$

$$\begin{aligned}
&= \frac{aT^2}{2} \sum_{k \in \mathbb{Z}_N} ((\beta^\dagger \Phi^{-1})_{k+1,k} - (\beta^\dagger \Phi^{-1})_{k+1,k}) \\
&= \frac{aT^2}{2} \sum_{k \in \mathbb{Z}_N} (M_{k,k+1} - M_{k+1,k}) = aT^2 N.
\end{aligned} \tag{6.5}$$

By (6.3), (6.4), (6.5) and the variational formula (6.2), we find that there exists a constant $C < +\infty$, independent of the realization of the disorder, of λ and of N , such that for any positive a ,

$$\frac{1}{NT^2} \mu_T(J_N(z-L)^{-1}J_N) \geq a - Ca^2 \left((z+2\lambda) + \frac{1}{z+4\lambda} \right).$$

By optimizing over a , this implies

$$\frac{1}{NT^2} \mu_T(J_N(z-L)^{-1}J_N) \geq \frac{1}{4C} \left((z+2\lambda) + \frac{1}{z+4\lambda} \right)^{-1}.$$

Since $\mathcal{J}_N = J_N/\sqrt{N}$, this shows (6.1). \square

Acknowledgments We thank J.-L. Lebowitz and J. Lukkarinen for their interest in this work and T. Bodineau for useful discussions. We thank C. Liverani, S. Olla and L.-S. Young, as organizers of the Workshop on the Fourier Law and Related Topics, as well as the kind hospitality of the Fields Institute in Toronto, where this work was initiated. C.B. acknowledges the support of the French Ministry of Education through the grants ANR-10-BLAN 0108. F.H. acknowledges the European Advanced Grant Macroscopic Laws and Dynamical Systems (MALADY) (ERC AdG 246953) for financial support.
