Reducibility theory and its applications to Schrödinger operators

Jiangong You

Nanjing University

February 5, 2015
Summary of the lecture

1. Introduction to quasi-periodic Schrödinger operator
2. Reducibility and Almost reducibility
3. Application 1: Kotani-Last Conjecture
4. Application 2: Dry Ten Martini Problem
5. Application 3: Aubry-André-Jitomirskaya conjecture

Based on joint works with A. Avila, X. Hou and Q. Zhou.
1. Introduction to quasi-periodic Schrödinger operator
2. Reducibility and Almost reducibility
Conductivity of Quasi-crystal.
Quantum Hall effect.
Evolution of Bose-Einstein condensate in a disordered lattice nonlinear optics.
Wave propagation in a nonlinear disordered media.
The mathematical modeling

The mathematical modeling for the above physical problems is the following quasi-periodic lattice nonlinear Schrödinger equations

\[ i \dot{q}_n + \epsilon (q_{n+1} + q_{n-1}) + V(n\alpha + x)q_n + \mu |q_n|^2 q_n = 0, \quad n \in \mathbb{Z} \quad (1) \]

where

- \( 0 < \epsilon \ll 1, 0 \leq \mu \ll 1 \),
- \( V \) is a non-constant real analytic function on \( \mathbb{R}/\mathbb{Z} \),
- \( \alpha \) satisfying the Diophantine condition.
- or the potential is independent identically distributed random variables.

To understand the dynamics of the above equation, understanding the corresponding operator \( H = \triangle + V \) is a crucial step.
In this lecture, we are interested in the discrete one-frequency quasi-periodic Schrödinger operator

\[(H_\theta u)_n = u_{n+1} + u_{n-1} + v(\theta + n\alpha)u_n, u \in l^2(\mathbb{Z})\]

where \(\alpha \in \mathbb{R}\setminus\mathbb{Q}, \theta \in \mathbb{T}, v(\theta) \in C^\omega(\mathbb{T}, \mathbb{R})\).

Continuous case

\[H_\theta(u) = -\frac{d^2 u}{dt^2} + v(\theta_1 + t, \theta_2 + t\alpha)u, u \in L^2(-\infty, \infty)\]
Typical Example: Almost Mathieu operators

\((H_{\lambda,\theta,\alpha} u)_n = u_{n+1} + u_{n-1} + 2\lambda \cos(n\alpha + \theta)u_n.\)

where \(\lambda\) is called the coupling constant, \(\alpha\) is called the frequency, \(\theta\) is called the phase.
Basic concepts

- Spectrum of $H_\theta$:

$$\Sigma(H_\theta) = \{ E \in \mathbb{C} \mid (H_\theta - E)^{-1} \text{ doesn't exist}\},$$

since $\theta \to \theta + \alpha$ is minimal, then $\Sigma(H_\theta) = \Sigma$ for any $\theta \in \mathbb{T}$.

- Spectral measure $\mu = \mu_{ac} + \mu_{sc} + \mu_{pp}$.

$$\langle (H_\theta - z)^{-1} f, f \rangle = \int_{\mathbb{R}} \frac{d\mu^f_\theta(t)}{t - z}, \quad f \in l^2(\mathbb{Z}).$$

- IDS (Integrated density of states)

$$N(E) = \int_{\mathbb{R}/\mathbb{Z}} \mu^f_\theta(-\infty, E] d\theta.$$
Central goal: Understanding the spectrum $\Sigma$ and the spectral measure of $H_\theta$ including

- Topology: topology of the spectrum $\Sigma$: For example, Ten Martini problem (Cantor set), Dry Ten Martini problem.
Spectral Theory for quasi-periodic Schrödinger operators

Central goal: Understanding the spectrum $\Sigma$ and the spectral measure of $H_\theta$ including

- Topology: topology of the spectrum $\Sigma$: For example, Ten Martini problem (Cantor set), Dry Ten Martini problem.

- Measure: the property of the spectral measure: absolutely continuous? singular continuous? pure point? Phase transition?
The eigenvalue equation

\[(H_\theta u)_n = u_{n+1} + u_{n-1} + \nu(n\alpha + \theta)u_n = Eu_n,\]

is equivalent to

\[
\begin{pmatrix}
u_{n+1} \\
u_n
\end{pmatrix} = \begin{pmatrix} E - \nu(n\alpha + \theta) & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} u_n \\
u_{n-1}
\end{pmatrix} = A^n \begin{pmatrix} u_1 \\
u_0
\end{pmatrix}
\]

where

\[
A^n = \begin{pmatrix} E - \nu(n\alpha + \theta) & -1 \\ 1 & 0 \end{pmatrix} \ldots \begin{pmatrix} E - \nu(\theta) & -1 \\ 1 & 0 \end{pmatrix}
\]
Schrödinger cocycle and $SL(2, \mathbb{R})$ cocycles

We shall call Schrödinger cocycle the map $(\alpha, S^v_E)$:

$$T \times \mathbb{R}^2 \to T \times \mathbb{R}^2$$

$$(\theta, w) \mapsto (\theta + \alpha, S^v_E(\theta) \cdot w),$$

where

$$S^v_E(\theta) = \begin{pmatrix} E - v(\theta) & -1 \\ 1 & 0 \end{pmatrix}.$$

Quasi-periodic $SL(2, \mathbb{R})$ cocycle $(\alpha, A)$ is more general:

$A : T \to SL(2, \mathbb{R})$. 
Continuous Schrödinger operator

Continuous version Schrödinger equation

\[ (\mathcal{L}_{\theta, q} u)(t) = -u''(t) + q(\theta + t\omega)u(t) = Eu(t). \]

can be rewritten as

\[
\begin{aligned}
\dot{x} &= \begin{pmatrix} 0 & 1 \\ q(\theta) - E & 0 \end{pmatrix} x \\
\dot{\theta} &= \omega
\end{aligned}
\]

Quasi-periodic \( sl(2, \mathbb{R}) \) linear system \((\omega, A)\) is defined as

\[
\begin{aligned}
\dot{x} &= A(\theta)x \\
\dot{\theta} &= \omega
\end{aligned}
\]
Lyapunov exponent

Let $A(\cdot) : \mathbb{T} \rightarrow SL(2, \mathbb{R})$ be continuous, it is a theorem due to Kingman that for a.e. $\theta \in \mathbb{T}$ the limit

$$\lim_{n \to \infty} \frac{1}{n} \log \| A^n(\theta) \|$$

exists and is same for a.e. $\theta \in \mathbb{T}$. We call this number Lyapunov exponent $L(\alpha, A)$. When $L(\alpha, A) > 0$ Oseledec Theorem tells us that for a.e. $\theta \in \mathbb{T}$,

- There exists a measurable decomposition $\mathbb{R}^2 = E_s(\theta) \bigoplus E_u(\theta)$. 

Let $A(\cdot) : \mathbb{T} \to SL(2, \mathbb{R})$ be continuous, it is a theorem due to Kingman that for a.e. $\theta \in \mathbb{T}$ the limit

$$\lim_{n \to \infty} \frac{1}{n} \log \|A^n(\theta)\|$$

exists and is same for a.e. $\theta \in \mathbb{T}$. We call this number Lyapunov exponent $L(\alpha, A)$. When $L(\alpha, A) > 0$ Oseledec Theorem tells us that for a.e. $\theta \in \mathbb{T}$,

- There exists a measurable decomposition $\mathbb{R}^2 = E_s(\theta) \oplus E_u(\theta)$.
- There exists $\rho > 0$ and $C(\theta)$ depending measurably on $\theta$ such that for a.e. $\theta \in \mathbb{T}$, any $v \in \mathbb{R}^2$

$$\forall n \geq 0, \forall v \in E_s(\theta), \|A^n(\theta)v\| \leq Ce^{-n\rho}\|v\|$$

$$\forall n \geq 0, \forall v \in E_u(\theta), \|A^{-n}(\theta)v\| \leq Ce^{-n\rho}\|v\|$$
We say that the cocycle \((\alpha, A)\) is **uniformly hyperbolic** if

1. There exists a decomposition \(\mathbb{R}^2 = E_s(\theta) \bigoplus E_u(\theta)\) where \(\theta \to E_{s,u}(\theta)\) are continuous.
2. There exists \(C, \rho\) such that for any \(\theta \in \mathbb{T}\), any \(v \in \mathbb{R}^2\)

\[
\forall n \geq 0, \forall v \in E_s(\theta), \|A^n(\theta)v\| \leq Ce^{-n\rho}\|v\|
\]

\[
\forall n \geq 0, \forall v \in E_u(\theta), \|A^{-n}(\theta)v\| \leq Ce^{-n\rho}\|v\|
\]

Notice that for all \(\theta \in \mathbb{T}\), \(\rho = \lim \frac{1}{n} \log \|A^n(\theta)v\|\).

\((\alpha, A)\) is called **non-uniformly hyperbolic** if \(L(\alpha, A) > 0\) and \((\alpha, A)\) is not uniformly hyperbolic.
The **fibred rotation number** measures how solutions wind around the origin in $\mathbb{R}^2$ in average. The continuous map

$$F : \mathbb{T} \times S^1 \longrightarrow \mathbb{T} \times S^1$$

$$(\theta, v) \mapsto \left( \theta + \alpha, \frac{A(\theta)v}{\|A(\theta)v\|} \right)$$

admits a continuous lift $\tilde{F} : \mathbb{T} \times \mathbb{R} \rightarrow \mathbb{T} \times \mathbb{R}$ of the form:

$$\tilde{F}(\theta, t) = (\theta + \alpha, t + f(\theta, t))$$

such that

$$f(\theta + 1, t + 1) = f(\theta, t) \quad \text{and} \quad p(t + f(\theta, t)) = \frac{A(\theta)p(t)}{\|A(\theta)p(t)\|}$$

Define the **fibred rotation number** as

$$\rho(\alpha, A) = \lim_{N \to \infty} \frac{1}{N} \sum_{n=0}^{N-1} f\left(\tilde{F}^n(\theta, t)\right)$$
Links between the spectral and dynamical aspects

- Spectrum and uniformly hyperbolic
- IDS and Lyapunov exponent
- IDS and the fibred rotation number
- AC spectrum and zero Lyapunov exponent: Kotani’s theory
- Spectrum and Reducibility
The spectrum of $H$ is the set of $E \in \mathbb{R}$ for which the cocycle $(\alpha, S^E)$ is not uniformly hyperbolic.
Theorem (Thouless formula)

\[ L(\alpha, S^v_E) = \int_{\mathbb{R}} \ln |E - t| dN(t) \]

where \( N(\cdot) \) is the IDS of the Schrödinger operator \( H \).
Theorem

\[ N(E) = 1 - 2\rho(\alpha, S^v_E). \]
Zero Lyapunov are highly related to the fact that the spectrum has some absolutely continuous part, which is known as Kotani’s theory.

**Theorem (Kotani’s theory)**

For $\text{Leb}$ a.e. $\theta \in \mathbb{T}$, one has $\Sigma_{ac}(H_\theta) = \{ E \in \mathbb{R} : L(E) = 0 \}$ (where $\Sigma_{ac}(H_\theta)$ is the essential support of the a.c. part of the spectrum).
The cocycle \((\alpha, A)\) is called **reducible**: if it is conjugated to a constant cocycle in the following sense: there exist an analytic map 
\(B : 2\mathbb{T} \to SL(2, \mathbb{R}), \ C \in SL(2, \mathbb{R})\) such that

\[
(0, B) \circ (\alpha, A) \circ (0, B)^{-1} = (\alpha, C)
\]

or equivalently

\[
B(\cdot + \alpha)A(\cdot)B(\cdot)^{-1} = C.
\]

Remark: Same concepts (LE, rotation number, reducibility, \ldots) can be defined for quasi-periodic linear system.
Reducibility is a very important concept, it can be used to study Cantor spectrum, Dry Ten Martini Problem, absolutely continuous spectrum, pure point spectrum ···. In the rest of the lecture, we will first establish various reducibility results.

1 Local reducibility
   ► Perturbative reducibility
   ► Nonperturbative reducibility
   ► Almost reducibility and rotations reducibility

2 Global reducibility
   ► Renormalization
   ► Avila’s global theory, Almost reducibility conjecture
Arithmetic property of $\alpha$

Arithmetic properties of $\alpha$ influence the spectrum and dynamics of the cocycle:

- **Diophantine $DC(\gamma, \tau)$:** $\|k\alpha\|_{\mathbb{R}/\mathbb{Z}} \geq \frac{\gamma}{|k|\tau}, k \neq 0$
Arithmetic property of $\alpha$

Arithmetic properties of $\alpha$ influence the spectrum and dynamics of the cocycle:

- Diophantine $DC(\gamma, \tau)$: $\| k \alpha \|_{\mathbb{R}/\mathbb{Z}} \geq \frac{\gamma}{|k|\tau}, k \neq 0$
- $DC = \bigcup \gamma, \tau DC(\gamma, \tau)$
Arithmetic property of $\alpha$

Arithmetic properties of $\alpha$ influence the spectrum and dynamics of the cocycle:

- **Diophantine** $DC(\gamma, \tau)$: $\|k\alpha\|_{\mathbb{R}/\mathbb{Z}} \geq \frac{\gamma}{|k|\tau}$, $k \neq 0$
- $DC = \bigcup \gamma, \tau DC(\gamma, \tau)$
- **Liouvillean**: $\beta(\alpha) := \limsup_{n \to \infty} \frac{\ln q_{n+1}}{q_n} > 0$, where $\frac{p_n}{q_n}$ is the fractal expansion of $\alpha$. 

Arithmetic property of $\alpha$

Arithmetic properties of $\alpha$ influence the spectrum and dynamics of the cocycle:

- **Diophantine** $DC(\gamma, \tau)$: $\|k\alpha\|_{\mathbb{R}/\mathbb{Z}} \geq \frac{\gamma}{|k|\tau}, k \neq 0$

- $DC = \bigcup_{\gamma, \tau} DC(\gamma, \tau)$

- **Liouvillean**: $\beta(\alpha) := \limsup_{n \to \infty} \frac{\ln q_{n+1}}{q_n} > 0$, where $\frac{p_n}{q_n}$ is the fractal expansion of $\alpha$.

- $DC \subset \{\alpha | \beta(\alpha) = 0\}$
Positive measure local reducibility results

Local reducibility: cocycle is close to constant

**Theorem (Dinaburg-Sinai)**

Let \( \alpha \in DC(\gamma, \tau), \gamma, \tau, \kappa, \sigma > 0, A_0 \in SL(2, \mathbb{R}), h > 0 \). There exists \( \varepsilon_0 = \varepsilon(\gamma, \tau, \kappa, \sigma, A_0, h) > 0 \), s.t. for all \( F_0 \in C^\omega_h(\mathbb{T}, sl(2, \mathbb{R})) \) satisfying

(i) \( \|F_0\|_h < \varepsilon_0 \),

(ii) \( 2\rho(\alpha, e^{F_0} A_0) \in DC_\alpha(\kappa, \sigma) = \{ \rho \in \mathbb{R} | \|\rho - k\alpha\|_{\mathbb{R}/\mathbb{Z}} \geq \frac{\kappa}{|k|\sigma}, k \neq 0 \} \),

the cocycles \( (\alpha, e^{F_0(\cdot)} A_0) \) is reducible on a strip of width \( h' = h/4 \).
Outline of the proof

• The strategy of the proof is typical of KAM theory (KAM for Kolmogorov, Arnold and Moser).
The strategy of the proof is typical of KAM theory (KAM for Kolmogorov, Arnold and Moser).

The philosophy of KAM theory is to construct a sequence of coordinate transformations making the perturbation smaller and smaller.
Outline of the proof

- The strategy of the proof is typical of KAM theory (KAM for Kolmogorov, Arnold and Moser).
- The philosophy of KAM theory is to construct a sequence of coordinate transformations making the perturbation smaller and smaller.
- Then, we have to prove that the compositions of all these transformations converge. This will finish the proof.
Outline of the proof

- Our aim is to find a conjugation \( B_1(\cdot) \) "close to the identity": \( B_1 = e^{Y_1} \) where \( Y_1 \) is small, \( Y_1 \in C^\omega_{\mathcal{h}_1}(\mathbb{T}, sl(2, \mathbb{R})) \) and a constant \( A_1 \in SL(2, \mathbb{R}) \), s.t.

\[
e^{Y_1(\cdot+\alpha)} e^{F_0(\cdot)} A_0 e^{-Y_1(\cdot)} = e^{F_1(\cdot)} A_1,
\]

with \( F_1 \) as small as possible.
Outline of the proof

- Our aim is to find a conjugation $B_1(\cdot)$ "close to the identity": $B_1 = e^{Y_1}$ where $Y_1$ is small, $Y_1 \in C^\omega_{h_1} (\mathbb{T}, sl(2, \mathbb{R}))$ and a constant $A_1 \in SL(2, \mathbb{R})$, s.t.

$$e^{Y_1(\cdot + \alpha)} e^{F_0(\cdot)} A_0 e^{-Y_1(\cdot)} = e^{F_1(\cdot)} A_1,$$

with $F_1$ as small as possible.

- Using the fact $e^M = I + M + O(M^2)$, $(I + M)^{-1} = I - M + O(M^2)$, we see that if we are seeking for $F_1$ to be 0, one has

$$Y_1(\cdot + \alpha) - A_0 Y_1(\cdot) A_0^{-1} = -F_0 + A_1 A_0^{-1} - I + O_2(\|Y_1\|_{h_1}, \|F_0\|_h).$$
Outline of the proof

- Our aim is to find a conjugation $B_1(\cdot)$ ”close to the identity”:
  $B_1 = e^{Y_1}$ where $Y_1$ is small, $Y_1 \in C^\omega_h(\mathbb{T}, \mathfrak{sl}(2, \mathbb{R}))$ and a constant $A_1 \in SL(2, \mathbb{R})$, s.t.

  $$e^{Y_1(\cdot+\alpha)}e^{F_0(\cdot)}A_0 e^{-Y_1(\cdot)} = e^{F_1(\cdot)}A_1,$$

  with $F_1$ as small as possible.

- Using the fact $e^M = I + M + O(M^2)$, $(I + M)^{-1} = I - M + O(M^2)$, we see that if we are seeking for $F_1$ to be 0, one has

  $$Y_1(\cdot + \alpha) - A_0Y_1(\cdot)A_0^{-1} = -F_0 + A_1A_0^{-1} - I + O_2(\|Y_1\|_h, \|F_0\|_h).$$

- Conversely,
Proposition

If one solves the linearized equation

\[ Y_1(\cdot + \alpha) - A_0 Y_1(\cdot) A_0^{-1} = -F_0 + A_1 A_0^{-1} - I, \]

with \( Y_1 \in C_{h_1}^\infty(\mathbb{T}, sl(2, \mathbb{R})) \), then we will have

\[ e^{Y_1(\cdot + \alpha)} (e^{F_0(\cdot) A_0}) e^{-Y_1(\cdot)} = e^{F_1(\cdot)} A_1, \]

with \( \|F_1\|_{h_1} = O_2(\|Y_1\|_{h_1}, \|F_0\|_h). \)
Linearized equation

Proposition

Assume that $A \in SL(2, \mathbb{R})$, $F \in C_{h}^{\omega}(\mathbb{T}, sl(2, \mathbb{R}))$, $\alpha \in DC(\gamma, \tau)$, $2\rho(\alpha, A) \in DC_{\alpha}(\kappa, \sigma)$. Then the equation

$$Y(\cdot + \alpha) - AY(\cdot)A^{-1} = F - \hat{F}(0)$$

has a unique analytic solution $Y \in C_{h}^{\omega}(\mathbb{T}, sl(2, \mathbb{R}))$ defined on some strip of width $h'$ for all $h' < h$, and s.t.

$$\|Y\|_{h'} \leq C(\gamma, \kappa) \frac{\|F\|_{h}}{(h - h')^{a}},$$

with $a = 2 + \tau + \sigma$. 
Solution of the linearized equation

The linearized equation (homological equation)

\[ Y(\cdot + \alpha) - AY(\cdot)A^{-1} = F - \hat{F}(0) \]

is equivalent to

\[
\begin{align*}
y_1(\theta + \alpha) - y_1(\theta) &= f_1(\theta) \\
y_2(\theta + \alpha) - e^{2\pi i \rho} y_2(\theta) &= f_2(\theta) \\
y_3(\theta + \alpha) - e^{-2\pi i \rho} y_3(\theta) &= f_3(\theta)
\end{align*}
\]

checking the Fourier coefficients, one knows if \( \alpha \in DC(\gamma, \tau) \), \( 2\rho \in DC_\alpha(\kappa, \sigma) \), then they have analytic solutions.
The iterative scheme

Let $h_n = h - \frac{h}{4} - \cdots - \frac{h}{2^{n+1}}$. We construct sequences $A_n, F_n, Y_n$, such that

(a) $A_n \in SL(2, \mathbb{R})$ and $Y_n, F_n \in C_{h_n}^\omega (\mathbb{T}, sl(2, \mathbb{R}))$;
The iterative scheme

Let $h_n = h - \frac{h}{4} - \cdots - \frac{h}{2^{n+1}}$. We construct sequences $A_n, F_n, Y_n$, such that

(a) $A_n \in SL(2, \mathbb{R})$ and $Y_n, F_n \in C^\omega_{h_n} (\mathbb{T}, sl(2, \mathbb{R}))$;

(b) $(0, e^{Y_n(\cdot)}) \circ (\alpha, e^{F_{n-1}(\cdot)} A_{n-1}) \circ (0, e^{Y_n(\cdot)})^{-1} = (\alpha, e^{F_n(\cdot)} A_n)$;
Let $h_n = h - \frac{h}{4} - \cdots - \frac{h}{2^{n+1}}$. We construct sequences $A_n, F_n, Y_n$, such that

(a) $A_n \in SL(2, \mathbb{R})$ and $Y_n, F_n \in C^\omega_{h_n}(\mathbb{T}, sl(2, \mathbb{R}))$;
(b) $(0, e^{Y_n(\cdot)}) \circ (\alpha, e^{F_{n-1}(\cdot)} A_{n-1}) \circ (0, e^{Y_n(\cdot)})^{-1} = (\alpha, e^{F_n(\cdot)} A_n)$;
(c) $2\rho(\alpha, A_n) \in DC_\alpha(\kappa, \sigma)$;
The iterative scheme

Let $h_n = h - \frac{h}{4} - \cdots - \frac{h}{2^{n+1}}$. We construct sequences $A_n, F_n, Y_n$, such that

(a) $A_n \in SL(2, \mathbb{R})$ and $Y_n, F_n \in C^\omega_{h_n}(\mathbb{T}, sl(2, \mathbb{R}))$;

(b) $(0, e^{Y_n(\cdot)}) \circ (\alpha, e^{F_{n-1}(\cdot)} A_{n-1}) \circ (0, e^{Y_n(\cdot)})^{-1} = (\alpha, e^{F_n(\cdot)} A_n)$;

(c) $2\rho(\alpha, A_n) \in DC_\alpha(\kappa, \sigma)$;

(d) If $\varepsilon_n := \|F_n\|_{h_n}$, then one has

$$\|Y_{n+1}\|_{h_n} \leq h_n^{-a} \varepsilon_n, \text{ and } \varepsilon_{n+1} \leq C h_n^{-a} \varepsilon_n^2;$$
Let $h_n = h - \frac{h}{4} - \cdots - \frac{h}{2^{n+1}}$. We construct sequences $A_n, F_n, Y_n$, such that

(a) $A_n \in SL(2, \mathbb{R})$ and $Y_n, F_n \in C^\omega_{h_n} (\mathbb{T}, \mathfrak{sl}(2, \mathbb{R}))$;

(b) $(0, e^{Y_n(\cdot)}) \circ (\alpha, e^{F_{n-1}(\cdot)} A_{n-1}) \circ (0, e^{Y_n(\cdot)})^{-1} = (\alpha, e^{F_n(\cdot)} A_n)$;

(c) $2\rho(\alpha, A_n) \in DC_\alpha(\kappa, \sigma)$;

(d) If $\varepsilon_n := \|F_n\|_{h_n}$, then one has

$$\|Y_{n+1}\|_{h_n} \leq h_n^{-a} \varepsilon_n, \text{ and } \varepsilon_{n+1} \leq C h_n^{-a} \varepsilon_n^2;$$

(e) $\|A_n - A_{n-1} e^{\hat{F}_{n-1}(0)}\| \leq \varepsilon_n$. 
Invariance of the rotation number

Why point (c) holds?

**Lemma**

Assume $A \in SL(2, \mathbb{R})$, if $\|F\|$ is small enough, then we have

$$|\rho(\alpha, e^{F(\cdot)}A) - \rho(A)| \leq \|F\|.$$ 

**Lemma**

If the conjugation $B(\cdot)$ is close to the identity, then

$$\rho(\alpha, B(\cdot + \alpha)A(\cdot)B(\cdot)^{-1}) = \rho(\alpha, A).$$
The iterative scheme

Point (d) shows that $\varepsilon_n$ goes to 0 very fast and then one has:

**Proposition**

*The limits* $A_* = \lim_{n \to \infty} A_n$, $B_*(\cdot) = \lim_{n \to \infty} e^{Y_n(\cdot)} \cdots e^{Y_1(\cdot)}$ *exist and* $B_* \in C^\omega_{h/4}(\mathbb{T}, SL(2, \mathbb{R}))$. *Thus one has*

$$(0, B_*) \circ (\alpha, e^{\mathcal{F}_0(\cdot)} A_0) \circ (0, B_*)^{-1} = (\alpha, A_*).$$
The same method works for continuous quasi-periodic linear system, and the base frequency can be any dimension.
Perturbative reducibility:

- The same method works for continuous quasi-periodic linear systems, and the base frequency can be any dimension.
- Eliasson’s breakthrough: $\varepsilon_0$ can be chosen independently of $\kappa$, which is a full measure result on the energy.
Perturbative reducibility:

- The same method works for continuous quasi-periodic linear system, and the base frequency can be any dimension.
- Eliasson’s break through: $\varepsilon_0$ can be chosen independently of $\kappa$, which is a full measure result on the energy.
- The preceding results are called perturbative, i.e., $\varepsilon_0$ depends on $\gamma$. 
Nonperturbative reducibility:

- Nonperturbative reducibility: $\varepsilon_0$ does not depend on $\gamma$. 

Puig, Avila-Jitomirskaya: for Schrödinger cocycle, there are nonperturbative results. Shortcoming: using the structure of Schrödinger operator, thus only works for Schrödinger cocycle.

Bourgain: If the base frequency $\alpha \in \mathbb{T}$, nonperturbative reducibility doesn't exist.
Nonperturbative reducibility:

- **Nonperturbative reducibility:** \( \varepsilon_0 \) does not depend on \( \gamma \).
- Puig, Avila-Jitomirskaya: for Schrödinger cocycle, there are nonperturbative results.
Nonperturbative reducibility:

- Nonperturbative reducibility: $\varepsilon_0$ does not depend on $\gamma$.
- Puig, Avila-Jitomirskaya: for Schrödinger cocycle, there are nonperturbative results.
- Shortcoming: using the structure of Schrödinger operator, thus only works for Schrödinger cocycle.
Nonperturbative reducibility:

- Puig, Avila-Jitomirskaya: for Schrödinger cocycle, there are nonperturbative results.
- Shortcoming: using the structure of Schrödinger operator, thus only works for Schrödinger cocycle.
- Bourgain: If the base frequency $\alpha \in \mathbb{T}^2$, nonperturbative reducibility doesn’t exist.
Theorem (Hou-Y Invent of Math)

Let $\alpha \in DC(\gamma, \tau), \gamma, \tau, \kappa, \sigma > 0, A_0 \in sl(2, \mathbb{R}), h > 0$. There exists $\varepsilon_0 > 0$ which depend on $A_0, h$ but doesn’t depend on $\gamma, \tau, \kappa, \sigma$ s.t. for all $F_0 \in C^\omega(\mathbb{T}^2, sl(2, \mathbb{R}))$ satisfying

(i) $\|F_0\|_h < \varepsilon_0$,

(ii) $2\rho(\omega, A + F) \in DC_\alpha(\kappa, \sigma),$

the quasi-periodic linear system

$$\begin{cases} 
\dot{x} = (A + F(\theta))x \\
\dot{\theta} = \omega = (\alpha, 1).
\end{cases}$$

is reducible.
Obstructions to reducibility

Obstructions due to arithmetics of \( \alpha \): Even in the simplest case where \( A = R\varphi(x) \), where \( \varphi(x + 1) = \varphi(x) \) is analytic, the cocycle is not reducible. since in general

\[
y(\theta + \alpha) - y(\theta) = f(\theta)
\]

doesn’t have analytic solution.
Almost reducibility: if there exist sequences of analytic matrix functions $B_n : 2\mathbb{T}^2 \to SL(2, \mathbb{R})$, $A_n \in sl(2, \mathbb{R})$ and a sequence of matrix functions $F_n : \mathbb{T}^2 \to sl(2, \mathbb{R})$ converging (analytically) to zero, such that the conjugacy $B_n$ conjugate $(\omega, A)$ to $(\omega, A_n + F_n)$.

Rotations reducible: if there exist $B \in C^\omega (2\mathbb{T}^2, SL(2, \mathbb{R}))$ and $R_{\phi(\theta)} \in C^\omega (\mathbb{T}^2, so(2, \mathbb{R}))$ such that $B$ conjugate $(\omega, A)$ to $(\omega, R_{\phi(\theta)})$.

These concepts can be defined similarly for quasi-periodic $SL(2, \mathbb{R})$ cocycles.
Almost reducibility for quasi-periodic linear system

Theorem (Hou-Y Invent of Math)

Let \( \alpha \in \mathbb{R} \setminus \mathbb{Q} \), \( A_0 \in \text{sl}(2, \mathbb{R}) \), \( h > 0 \). There exists \( \varepsilon_0 = \varepsilon_0(A_0, h) > 0 \) s.t. for all \( F_0 \in C^\omega(T^2, \text{sl}(2, \mathbb{R})) \) satisfying \( \|F_0\|_h < \varepsilon_0 \), the quasi-periodic linear system

\[
\begin{align*}
\dot{x} &= (A + F(\theta))x \\
\dot{\theta} &= \omega = (\alpha, 1).
\end{align*}
\]

is almost reducible.
As we did in Dinaburg-Sinai’s result, one needs to find a constant matrix $\tilde{A}$ and $sl(2, \mathbb{R})$–valued function $Y(\theta)$ which solves

$$\partial_\omega e^Y = (A + F)e^Y - e^Y \tilde{A}.$$  

in this case, the linearized equation is

$$\partial_\omega Y - [A, Y] = F$$

(Lie bracket $[\cdot, \cdot]$ is defined as $[X_1, X_2] = X_1X_2 - X_2X_1$).
One step in our proofs is to remove all the non-resonant components in the Fourier expansion of $F$. For any given $h > 0$, $\omega \in \mathbb{R}^2$ and $A \in sl(2, \mathbb{R})$, we decompose $\mathcal{B}_h = \mathcal{B}_h^{(nre)} \oplus \mathcal{B}_h^{(re)}$ (the decomposition depends on $A, \omega, \eta$) in such a way that for any $Y \in \mathcal{B}_h^{(nre)}$

$$\partial_\omega Y, [A, Y] \in \mathcal{B}_h^{(nre)}, \quad |\partial_\omega Y - [A, Y]|_h \geq \eta |Y|_h.$$ 

Let $\mathbb{P}_{nre}$ ($\mathbb{P}_{re}$) be the standard projection from $\mathcal{B}_h$ onto $\mathcal{B}_h^{(nre)}$ ($\mathcal{B}_h^{(re)}$). We call $\mathcal{B}_h^{(nre)}$ ($\mathcal{B}_h^{(re)}$) the $\eta$-nonresonant ($\eta$-resonant) subspace. With the above assumptions, one can prove the following Lemma.
Step 1: Eliminating the non-resonant terms

Let $(h_n, \varepsilon_n) = (\frac{1}{8}h_{n-1}, \varepsilon_{n-1}e^{-cq_nh_{n-1}})$,

Lemma

The system is conjugated to

\[
\begin{cases}
    \dot{x} = (A + F^{(re)}(\theta))x \\
    \dot{\theta} = \omega = (\alpha, 1)
\end{cases}
\]

with $F^{(re)}$ containing only resonant terms of the Fourier expansion.
Moreover, $\|F^{(re)}\|_{h_n} < 2\varepsilon_n$.

Proof: Implicit Function Theorem.
The structure of Resonances

Let \( \alpha \in (0, 1) \) be irrational, \( \frac{p_n}{q_n} \) be its continued fraction expansion. Let \( \omega = (\alpha, 1) \). We know that

\[
\frac{1}{q_n+1 + q_n} < |q_n \alpha - p_n| < \frac{1}{q_n+1}.
\]

Lemma (The structure of resonances)

*Suppose that \( k \in \mathbb{Z}^2 \) with \( |k| < \frac{1}{6} q_{n+1} \) satisfies \( |\langle k, \omega \rangle| < \frac{1}{7q_n} \). Then \( k \) has the form \( l(q_n, -p_n) \) for some \( l \in \mathbb{Z} \).*
The structure of Resonances

\[ \mathcal{T}_{q_n+1} F^{(re)}(\theta) = \sum_{k \in \Lambda_1} \begin{pmatrix} \hat{F}_{11}(k) & 0 \\ 0 & -\hat{F}_{11}(k) \end{pmatrix} e^{i\langle k, \theta \rangle} + \left( \begin{array}{cc} 0 & \sum_{k \in \Lambda_2} \hat{F}_{12}(k) e^{i\langle k, \theta \rangle} \\ \sum_{k \in \Lambda_3} \hat{F}_{12}(k) e^{i\langle k, \theta \rangle} & 0 \end{array} \right). \]

with

\[ \Lambda_1 = \{ k \in \mathbb{Z}^2 | k = l(q_n, -p_n), l \in \mathbb{Z} \} \]
\[ \Lambda_2 = \{ k \in \mathbb{Z}^2 | k = k_\ast + l(q_n, -p_n), l \in \mathbb{Z} \} \]
\[ \Lambda_3 = \{ k \in \mathbb{Z}^2 | k = -k_\ast + l(q_n, -p_n), l \in \mathbb{Z} \} \]
Step 2: Rotation

Lemma

There exists $R \in C^\omega (\mathbb{T}^2, SO(2, \mathbb{R}))$ which conjugates the above system to

$$
\begin{align*}
\dot{x} &= (A_1 + F_1(\theta))x \\
\dot{\theta} &= \omega = (\alpha, 1)
\end{align*}
$$

with $|A_1| \leq \varepsilon_n^{1/2}$, $\|F_1\|_{h_n/4} < 2\varepsilon_n^{3/4}$. and $F_1$ takes the following form

$$
\mathcal{T}_{q_{n+1}/6} F_1 = \sum_{k=l(q_n,-p_n), |k|<\frac{q_{n+1}}{6}} \hat{F}_1(k) e^{i\langle k, \theta \rangle}.
$$

Remark Compared to Eliasson’s perturbative result: If $\alpha$ is Diophantine, then $\mathcal{T}_{q_{n+1}/6} F_1 = 0$. 
Step 3: Floquet

Lemma

There exists \( B \in C_{\omega}^{\omega h_{n+1}}(2\mathbb{T}^2, SL(2, \mathbb{R})) \) which conjugates (??) to

\[
\begin{aligned}
\dot{x} &= (A_2 + F_2(\theta))x \\
\dot{\theta} &= \omega = (\alpha, 1)
\end{aligned}
\]

with estimates \( \|F_2\|_{h_{n+1}} \leq \varepsilon_{n+1} \)

Proof:
Using the structure,

\[
\begin{aligned}
\dot{x} &= (A_1 + \mathcal{T}_{q_{n+1}} F_1(\theta))x \\
\dot{\theta} &= \omega
\end{aligned}
\]

is a periodic system, which can be conjugated to constant systems.
More discussion:

- Completely understanding of the local almost reducibility
- Shortcoming of the method: only works for continuous version
- Solution?
A local embedding theorem

**Theorem (Y-Zhou, CMP)**

Let $\mu \in \mathbb{T}^{d-1}$, $h > 0$, $G \in C_{h}^{\omega}(\mathbb{T}^{d-1}, sl(2, \mathbb{R}))$, $A$ is a constant. There exists a $\varepsilon > 0$, such that if $\|G\|_{h} \leq \varepsilon$, then there exists a $C^{\omega}$ quasi-periodic flow $\Phi_{t}(\theta_{1}, \tilde{\theta})$, such that $\Phi_{1}(0, \tilde{\theta}) = e^{A}e^{G(\tilde{\theta})}$. More precisely, there exists a $F \in C_{h/1+|\mu|}^{\omega}(\mathbb{T}^{d}, sl(2, \mathbb{R}))$ such that $(\mu, e^{A}e^{G(\cdot)})$ can be embedded into

\[
\begin{cases}
\dot{x} = (A + F(\theta))x \\
\dot{\theta} = (1, \mu)
\end{cases}
\]

with the estimate $\|F\|_{h/1+|\mu|} \leq c\varepsilon$.

It is true for any dimension!
With the embedding theorem, we prove the following equivalence of almost reducibility of linear systems and the corresponding Poincaré cocycles.

**Theorem (Y-Zhou, CMP)**

Quasi-periodic linear systems $(\omega, A)$ is almost reducible (resp. rotations reducible) if and only if the corresponding Poincaré cocycle $(\alpha, A)$ is almost reducible (resp. rotations reducible).
Rotations reducibility for cocycles

**Theorem (Hou-Y Invent of Math)**

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$, $h > 0$. $F \in C^\omega_h(\mathbb{T}^2, sl(2, \mathbb{R}))$. Assume that

$$2\rho(\alpha, e^{F(\cdot)}R_{\rho_0}) \in DC_\alpha(\gamma, \tau).$$

Then there exists $\varepsilon_0 = \varepsilon_0(\gamma, \tau, h)$, s.t. if $\|F\|_h \leq \varepsilon_0$, then the cocycle is rotations reducible.

**Remark** Similar result was obtained by Avila-Fayad-Krikorian [GAFA], but using quite different method.
Step 1: Rotation

Let $L_n = \gamma(8q_n)^\tau$, $(h_n, \varepsilon_n) = (h_{n-1} - \frac{r_{n-1}}{2}, \varepsilon_{n-1}e^{-\frac{qnr_{n-1}}{8L_{n-1}}})$.

We start with cocycle $(\alpha, e^{F(\cdot)}R_{\varphi(\cdot)})$ satisfying estimate $\|F\|_{h_n} \leq \varepsilon_n$.

Lemma

The cocycle $(\alpha, e^{F(\cdot)}R_{\varphi(\cdot)})$ can be conjugated by $(0, R_{\psi(\cdot)})$ to $(\alpha, e^{F_1(\cdot)}R_{\rho})$, where

$$\psi(\cdot + \alpha) - \psi(\cdot) = -T_{q_n}\varphi(\cdot) + \hat{\varphi}(0),$$

and $\rho = \hat{\varphi}(0) = \rho(\alpha, e^{F(\cdot)}R_{\varphi(\cdot)})$, $\|F_1\|_{h_n} \leq \varepsilon_n^{8/9}$.

Reducibility and applications

February 5, 2015

50 / 1
Lemma (The structure of resonances)

Let $\gamma > 0$, $\tau > 1$ and $\rho \in \text{DC}_\alpha(\gamma, \tau) \cap [-1, 1]$. Then for any $k \in \mathbb{Z}$ satisfying $|k| \leq q_{n+1}/L_n$, we have

$$\|k\alpha - 2\rho\|_\mathbb{Z} \geq \frac{1}{L_n}.$$
Step 2: Eliminating the non-resonant terms

**Lemma**

If \( \rho \in DC_\alpha(\gamma, \tau) \), then there exists \( Y_1 \in C_{h_n}^\omega(\mathbb{T}, sl(2, \mathbb{R})) \), s.t.

\[
(0, e^{Y_1(\cdot)}) \circ (\alpha, e^{F_1(\cdot)} R_{\rho}) \circ (0, e^{Y_1(\cdot)})^{-1} = (\alpha, e^{F_2(\cdot)} R_{\rho + \tilde{\psi}}).
\]

with

\[
T_{q_{n+1}/L_n} F_2 = 0,
\]

and

\[
\|Y_1\|_{h_n} \leq \varepsilon_n^{4/9}, \quad \|F_2\|_{h_{n+1}} \leq c\varepsilon_n^{7/9} e^{-\frac{q_{n+1} r_n}{4L_n}}.
\]

**Proof:** Implicit Function Theorem
Lemma

The cocycle \((\alpha, e^{F_2(\cdot)} R_{\rho+\tilde{\phi}(\cdot)})\) can be conjugated by \((0, R_{-\psi(\cdot)})\) to 
\((\alpha, e^{F_+(\cdot)} R_{\varphi_+})\), with 
\[
\|\varphi_+ - \varphi\|_{h_{n+1}} \leq 2\varepsilon_n^{8/9}, \quad \|F_+\|_{h_{n+1}} \leq \varepsilon_{n+1}.
\]
We construct sequences $\varphi_n, F_n, Y_n$, such that

(a) $\varphi_n \in C_h^\omega (\mathbb{T}, \mathbb{R})$ and $Y_n, F_n \in C_h^\omega (\mathbb{T}, sl(2, \mathbb{R}))$;
(b) $(0, e^{Y_n(\cdot)}) \circ (\alpha, e^{F_n(\cdot)} R_{\varphi_n(\cdot)}) \circ (0, e^{Y_n(\cdot)})^{-1} = (\alpha, e^{F_{n+1}(\cdot)} R_{\varphi_{n+1}(\cdot)})$;
(c) $2 \rho (\alpha, e^{F_n(\cdot)} R_{\varphi_n(\cdot)}) \in DC_\alpha (\kappa, \sigma)$;
(d) $\|Y_n\|_{h_n} \leq \varepsilon_n^{1/4}$, and $\|F_n\|_{h_{n+1}} \leq \varepsilon_{n+1}$.
(e) $\|\varphi_{n+1} - \varphi_n\|_{h_{n+1}} \leq \varepsilon_{n}^{8/9}$. 
Avila-Krikorian: if $\alpha$ is recurrent Diophantine, then for Lebesgue a.e. $\varphi \in [0, 1]$, $(\alpha, R_\varphi A(\cdot))$ is either $C^\omega$ reducible or non-uniformly hyperbolic.

Avila, Fayad and Krikorian: for any $\alpha \in \mathbb{R}\setminus\mathbb{Q}$, and for Lebesgue a.e. $\varphi \in [0, 1]$, $(\alpha, R_\varphi A(\cdot))$ is either $C^\omega$ rotations reducible or non-uniformly hyperbolic.

Method: Renormalization. Global to local reduction
Avila’s global theory of analytic quasiperiodic $SL(2, \mathbb{R})$ cocycle: cocycles which are not uniformly hyperbolic can be classified into three cases: subcritical, supercritical, critical.
Avila’s global theory of analytic quasiperiodic $SL(2, \mathbb{R})$ cocycle: cocycles which are not uniformly hyperbolic can be classified into three cases: subcritical, supercritical, critical.

**Subcritical**: the cocycle $(\alpha, A)$ is subcritical if there exists $\kappa > 0$, such that $L(\alpha, A(\cdot + i\varepsilon)) = 0$ for $|\varepsilon| < \kappa$. 
Avila’s global theory of analytic quasiperiodic $SL(2, \mathbb{R})$ cocycle: cocycles which are not uniformly hyperbolic can be classified into three cases: subcritical, supercritical, critical.

**Subcritical**: the cocycle $(\alpha, A)$ is subcritical if there exists $\kappa > 0$, such that $L(\alpha, A(\cdot + i\varepsilon)) = 0$ for $|\varepsilon| < \kappa$.

**Almost reducibility conjecture (ARC)**: subcritical implies almost reducibility.
Global reducibility 2: Almost reducibility conjecture

Theorem (Avila)

For any $\alpha \in \mathbb{R} \setminus \mathbb{Q}$, $A \in C^\omega(\mathbb{T}, SL(2, \mathbb{R}))$, $(\alpha, A)$ is almost reducible if it is subcritical.
Lecture 2: Applications

1. Application 1: Kotani-Last Conjecture
2. Application 2: Dry Ten Martini Problem
3. Application 3: Aubry-André-Jitomirskaya conjecture
Application 1: Counter-example to Kotani-Last conjecture

As the first application of reducibility theory, we will give a simple counterexample to Kotani-Last Conjecture.
Setting: Ergodic Schrödinger operator

Continuous ergodic family of Schrödinger operators

\[ (\mathcal{L}_\theta y)(t) = -y''(t) + V_\theta(t)y(t). \]

with potentials

\[ V_\theta(t) = v(T^t(\theta)), \quad \theta \in \Theta, \quad t \in \mathbb{R}, \]

where \((\Theta, \mathcal{B}, \mu, T^t)\) is ergodic and \(v : \Theta \to \mathbb{R}\) is measurable and bounded. The discrete counterparts are the ergodic Schrödinger operators

\[ (H_\theta u)_n = u_{n+1} + u_{n-1} + V_\theta(n)u_n \]

in \(l^2(\mathbb{Z})\), where \(V_\theta(n) = v(F^n(\theta))\) and \(F\) is an ergodic map.
Examples

Take \((\Theta, B, \mu, T^t)\) to be \((T^d, m, R_\omega)\) where \(\omega\) is rational independent. This is the so called quasi-periodic Schödinger operators. By Dinaburg-Sinai and Eliasson’s result, the operator might have ac spectrum.

On the other hand, if \((\Theta, B, \mu, T^t)\) is very ”chaotic”, then Lyapunov exponent are always positive. Then there is no ac spectrum, which is due to Kotani’s theory.

Question: if an operator has ac spectrum, how regular the potential \(v(T^t\theta)\) can be?
Kotani-Last Conjecture, 1980’ If $\Sigma_{ac} \neq \emptyset$, then the potential $V_\theta(\cdot)$ is almost periodic.
Simple counterexample to Kotani-Last conjecture

**Theorem (Y-Zhou, IMRN, online 2014)**

There exists non-almost periodic potential $V_{\theta}(t) = v(T^t(\theta))$ which is a composition by weak mixing flows $T^t(\theta)$ and non-constant analytic functions $v(\theta)$ on 2-torus, such that the Schrödinger operators $L$ with $V_{\theta}(t)$ have absolutely continuous spectrum.
Almost periodic and weak-mixing

- **Almost periodic**: a function $f$ is called almost periodic if every sequence $f(t + T_n)$ of translation of $f$ has a subsequence converging uniformly in $t \in \mathbb{R}$.

- **Weak-mixing**: For all $f, g \in L^2(\mu)$, we have

$$\lim_{N \to \infty} \frac{1}{N} \sum_{n=0}^{N-1} \left| \int f(T^n x) g(x) d\mu - \int f(x) d\mu \int g(x) d\mu \right| = 0$$

- Basic facts from ergodic theory, if $T$ is weakly mixing, then it is not almost periodic.
Subordinacy theory

Theorem (Gilbert-Pearson)

Let $B$ be the set of $E \in \mathbb{R}$ such that the generalized eigenfunctions of the operator $\mathcal{L}$ with energy $E$ are bounded, i.e.,

$$B = \{ E : \text{ all solutions of } Lu = Eu \text{ are bounded} \}$$

If $B$ has positive Lebesgue measure, then the operator has absolutely continuous spectrum.
Reducibility implies absolutely continuous spectrum:

- Subordinacy theory: bounded eigenfunctions implies absolutely continuous spectrum.
Reducibility implies absolutely continuous spectrum:

- Subordinacy theory: bounded eigenfunctions implies absolutely continuous spectrum.
- Positive measure reducibility implies absolutely continuous spectrum.
Reducibility implies absolutely continuous spectrum:

- Subordinacy theory: bounded eigenfunctions implies absolutely continuous spectrum.
- Positive measure reducibility implies absolutely continuous spectrum.
- Reducibility can be replaced by rotations reducibility.
Ac spectrum with quasi-periodic potential:

Quasi-periodic potential:

\[(\mathcal{L}_\theta y)(t) = -y''(t) + V(\theta + \omega t)y(t).\]  \hspace{1cm} (4)

with \(\omega = (1, \alpha)\).

Dinaburg-Sinai, Eliasson, Avila-Fayad-Krikorian, Hou-Y: If \(V\) is small, then \(\mathcal{L}_\theta\) has absolutely continuous spectrum.

Reason: Positive measure reducibility (rotations reducibility).
Reparameterized linear flow

Base dynamics is given by the reparameterized linear flow:

\[
\frac{d\theta}{dt} = \frac{1}{\phi(\theta)}(1, \alpha)
\]  \hspace{1cm} (5)

where \( \alpha \in \mathbb{R}\backslash \mathbb{Q} \), \( \phi \in C^\omega(T^2, \mathbb{R}) \).

Fayad: If \( \beta(\alpha) > 0 \), for a dense \( G_\delta \) subset \( \mathcal{H} \) of functions \( \phi \) in the space of analytic positive functions, the reparameterized flow \( T^t \) of \( \frac{1}{\phi(\theta)}(1, \alpha) \) is weak mixing.

Let \( v_\theta(t) = f(T^t\theta) \) with non-constant \( f \), then the operator with potential \( v_\theta(t) \) is not almost periodic.
Time-rescaling

The eigenvalue equation $\mathcal{L}_\theta y = Ey$ is equivalent to

$$
\begin{align*}
\dot{x} &= \begin{pmatrix} 0 & 1 \\ v(\theta) - E & 0 \end{pmatrix} x \\
\dot{\theta} &= \frac{1}{\phi(\theta)}(1, \alpha).
\end{align*}
$$

(6)

and we rescale the time, and transform (??) into

$$
\begin{align*}
\frac{dx}{ds} &= \begin{pmatrix} 0 & \phi(\theta) \\ \phi(\theta)(v(\theta) - E) & 0 \end{pmatrix} x \\
\frac{d\theta}{ds} &= (1, \alpha)
\end{align*}
$$

Assume that $\phi(\theta) = 1 + f(\theta) \in \mathcal{H}$ with $f$ being small enough.
Key point of the proof:

- Time-rescaling
- Positive measure rotations reducibility
- Subordinacy theory
Counterexample to Kotani-Last conjecture:

- **Avila (JAMS, 2014):** both continuous and discrete potential
  - Method: periodic approximation, direct construction, powerful but complicated, base dynamics: weak-mixing
- **Volberg and Yuditskii (Inventiones Math, 2014):** discrete potential
  - Method: inverse spectral theory, indirect construction, complicated, the dynamics of the base is unclear.
Application 2: Dry Ten Martini Problem

In the rest of the lectures, we will focus on the application of reducibility theory to Almost Mathieu operators.

\[(H_{\lambda,\theta,\alpha}u)_n = u_{n+1} + u_{n-1} + 2\lambda \cos(n\alpha + \theta)u_n.\]

We first talk about Dry Ten Martini Problem.
Ten Martini problem: the spectrum of almost Mathieu operators is a Cantor set? or equivalently,

Uniformly hyperbolic cocycles are the dense in the one parameter family $(\alpha, S_E^{2\lambda \cos})$ for all fixed $\lambda \neq 0$ and irrational $\alpha$.

Conjecture by Azbel 64;

Ten Martini problem

*Ten Martini problem is true for \( \lambda = 1 \).*

*Ten Martini problem is true for all \( \lambda \neq 1 \).*
Spectral gaps: intervals in the complimentary of the spectrum set.

Theorem (Johnson-Moser, 1982)

In each spectral gap, the rotation number is a constant of the form
\[ \frac{1}{2} \{n \alpha\}, \quad n \in \mathbb{Z}. \]
Dry Ten Martini problem

- **Dry Ten Martini problem**: Do all possible gaps open? More precisely, if the set
  \[ \{ E \in \mathbb{R} \mid 2\rho(E) = \{ n\alpha \} \} \]
  is an open set for all \( n \)?

- **Dry Ten Martini Problem**: for all \( \lambda \neq 0 \), all irrational \( \alpha \), and all integers \( n_1, n_2 \) with \( 0 < n_1 + n_2\alpha < 1 \), there is a gap for \( H_{\lambda,\alpha,\theta} \) on which \( N_{\lambda,\alpha}(E) = n_1 + n_2\alpha \).

- It is obvious that Dry Ten Martini problem implies Ten Martini problem.
Why called Dry Ten Martini problem?

In 1980’s Kac hoped to know, if all possible gaps are open for almost Mathieu operators. He offered a reward of ten Martini (wine) to those people who can prove it.

Thereafter, Simon named the problems:

The weak version of the problem (Cantor spectrum) was called the Ten Martini problem;

The strong (original) version of the problem (all gaps open) was called the Dry Ten Martini problem.
Known results in Dry Ten Martini problem

- Puig (CMP, 2006): Dry Ten Martini problem holds if $\alpha$ is Diophantine and $\lambda$ small.
- Avila-Jitomirskaya (Ann. Math., 2009): if $\alpha$ is Diophantine and $\lambda \neq 0, \pm 1$ and $e^{-\beta} < \lambda < e^\beta$. 
Theorem (Avila-Y-Zhou)

If $\alpha \in \mathbb{R} \setminus \mathbb{Q}$, $\lambda \neq 0$, then $H_{\lambda,\alpha,\theta}$ has all spectral gaps open for all $(\lambda, \beta(\alpha)) \neq (\pm 1, 0)$.

Remark: $\Sigma_{\lambda} = \Sigma_{\lambda-1} = \Sigma_{-\lambda}$, therefore we only need to consider the case $0 < \lambda < 1$. 
Aubry duality

Aubry duality from the point of view of reducibility

\[ B(\theta + \alpha)^{-1} S_E^{2\lambda \cos(\theta)} B(\theta) = \begin{pmatrix} e^{2\pi i \phi} & 0 \\ 0 & e^{-2\pi i \phi} \end{pmatrix}, \]

and write \( B(\theta) = \begin{pmatrix} B_{11}(\theta) & B_{12}(\theta) \\ B_{21}(\theta) & B_{22}(\theta) \end{pmatrix}, \) then we have

\[ (E - 2\lambda \cos(\theta))B_{11}(\theta) = B_{11}(\theta - \alpha)e^{-2\pi i \phi} + B_{11}(\theta + \alpha)e^{2\pi i \phi}. \] (7)

Taking the Fourier transformation for (??), we have

\[ \hat{B}_{11}(n + 1) + \hat{B}_{11}(n - 1) + 2\lambda^{-1} \cos 2\pi(\phi + n\alpha)\hat{B}_{11}(n) = \lambda^{-1} E\hat{B}_{11}(n), \]

Say \( B_{11}(\theta) \) is (analytic) block wave, and \( \hat{B}_{11}(n) \) are eigenfunction of the dual Mathieu operator.
Strategy of the proof in Diophantine case

- the cocycle \((\alpha, S^2_\lambda \cos)\) is reducible for \(\rho(E) = \frac{1}{2}\{k\alpha\}\) when \(0 < \lambda < 1\). When \(\lambda\) is small, this is a consequence of the famous result of Eliasson in his 1992 paper. For \(0 < \lambda < 1\), it is proved by Avila-Jitomirskaya later.

- \((\alpha, S^2_\lambda \cos)\) for \(\rho(E) = \frac{1}{2}\{k\alpha\}\) can not be reduced to the identity. Otherwise, using Aubry dual, it contradicts to the simplicity of eigenvalues.

- Thus the reduced one is parabolic. One can use Moser-Pöschel argument to prove the corresponding gap is open.
Limitation of the method

- If $\beta(\alpha) > 0$, Diophantine approach can’t cover all the rest parameter.
- Jitomirskaya: “even after pushing the existing approaches to absolute technique limits, there still exists parameter belongs to the arithmetically critical regime.”
- Solution: replace reducibility by Almost reducibility
Let $D_n = \begin{pmatrix} 1 & d_n \\ 0 & 1 \end{pmatrix}$.

**Proposition**

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$ with $\beta(\alpha) > 0$, for any fixed $k_0 \in \mathbb{Z}$, if $(\alpha, A)$ is subcritical with $2\rho(\alpha, A) = k_0 \alpha \mod \mathbb{Z}$, then there exist $n = n_{k_0}$, $B_n(\theta) \in C^\omega_{h_n}(2\mathbb{T}, SL(2, \mathbb{R}))$ with $\|B_n\|_{h_n} \leq e^{2qn+1\varepsilon_n}$, such that

$$B_n(\theta + \alpha)^{-1}A(\theta)B_n(\theta) = A_n + F_n(\theta)$$

(8)

where $A_n = \text{id}$ (or $A_n = D_n$), $\|F_n\|_{h_n} \leq e^{-cq_n+1\delta_n}$, and $\varepsilon_n << \delta_n$. 

J. You

Reducibility and applications

February 5, 2015
Proof of almost reducibility

- Three main ingredients
- Avila’s solution of almost reducibility conjecture: reduce to local regime.
- Y-Zhou [CMP,2013]: local embedding theorem, embed local cocycle into the flow.
- Hou-Y [Invention 2012]: local almost reducibility for continuous quasi-periodic linear system.
- Why we need local embedding theorem?
Almost reducibility conjecture in case $\beta(\alpha) > 0$

**Theorem (Avila)**

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$ with $\beta(\alpha) > 0$, and $(\alpha, A)$ is subcritical, then there exists $C > 0$, such that if $\delta > 0$ is sufficiently small, then there exist $N = N(\alpha, \delta), \ h = h(C, \delta) > 0, \ R_{\varphi_n} \in SO(2, \mathbb{R})$ such that

$$B_n(\theta + \alpha)^{-1} A(\theta) B_n(\theta) = R_{\varphi_n} + F_n(\theta)$$

where $n \geq N(\alpha, \delta)$, and $\|B_n\|_h \leq e^{Cq_n\delta}$, $\|F_n\|_h \leq e^{-q_n\delta}$.

**Remark:** The growth of conjugation $B_n$ is much faster than the decay of the perturbation $F_n$. 
If $0 < \lambda < 1$, then for any $E \in \Sigma_\lambda$, $(\alpha, S^2_\lambda \cos) \text{ is subcritical}$. Suppose that $E_k \in \Sigma_\lambda$ such that $\rho(\alpha, S^2_\lambda \cos) = k\alpha \text{ mod } \mathbb{Z}$. By quantitative almost reducibility, the cocycle is reduced to $A_n + F_n(\theta)$ by $B_n(\theta)$ with $\|B_n\|^{-1} \gg \|F_n\| \to 0$ and $A_n$ being constants. Take $N$ sufficiently large. There are two cases.

Case 1. $A_N = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, we need the following:
Proof of Dry Ten Martini: Case 1

**Proposition**

Let $\alpha \in \mathbb{R}\setminus\mathbb{Q}$, $0 < \lambda < 1$, $E \in \Sigma_\lambda$, there exists $C = C(h, \lambda)$, such that for $\varepsilon$ sufficiently small, there exists no $B(\theta) \in C^\omega_h(2\mathbb{T}, SL(2, \mathbb{R}))$ such that

$$B(\theta + \alpha)^{-1}S^\lambda_E(\theta)B(\theta) = id + F(\theta)$$

(10)

with estimate $\|B\|_h \leq \varepsilon^{-1}$, $\|F\|_h \leq \varepsilon^C$.

**Proof:** $B_{11}(\theta)$ and $B_{12}(\theta)$ are two approximating linearly independent Block waves. By Aubry dual, their coefficients are two approximating eigenvectors. This contradicts to the preservation of Wronskian.
Proof of Dry Ten Martini: Case 2

The second case:

Case 2. \( A_N = \begin{pmatrix} 1 & c_N \\ 0 & 1 \end{pmatrix} \) with \(|c_N| \neq 0\) relatively big.

In this case, we will prove that, there is a \( \delta_k > 0 \), such that the rotation number of \( (\alpha, S^{2\lambda \cos}_E) \) is same as that of \( (\alpha, S^{2\lambda \cos}_{E_k}) \) for \( E \in (E_k + \delta_k, E_k + 2\delta_k) \) or for \( E \in (E_k - 2\delta_k, E_k - \delta_k) \). This implies that the gap corresponding to \( \rho(\alpha, S^{2\lambda \cos}_E) \) is open.
Problem remained

All gaps are open in the critical case $\lambda = 1$. Then Dry Ten Martini problem is closed.
The third application of the reducibility theory: Phase transition for almost Mathieu operators.

\[(H_{\lambda, \theta, \alpha} u)_n = u_{n+1} + u_{n-1} + 2\lambda \cos(n\alpha + \theta) u_n.\]
In 1980, Aubry-André conjectured that the spectral measure of $H_{\lambda,\alpha,\theta}$ depends on $\lambda$ in the following way:

- If $\lambda < 1$, then $H_{\lambda,\alpha,\theta}$ has purely absolutely continuous spectrum for all $\alpha \in \mathbb{R}\setminus\mathbb{Q}$, and all $\theta \in \mathbb{R}$.
- If $\lambda > 1$, then $H_{\lambda,\alpha,\theta}$ has pure point spectrum for all $\alpha \in \mathbb{R}\setminus\mathbb{Q}$ and almost all $\theta \in \mathbb{R}$.

Avron-Simon[Bull A.M.S 1982]: this conjecture is wrong, arithmetic property of $\alpha$ has to be taken into account.
Jitomirskaya [Ann. of Math, 1999] settles Aubry-André’s conjecture in the measure setting: if $\alpha \in DC$, then

- If $\lambda < 1$, then $H_{\lambda,\alpha,\theta}$ has purely absolutely continuous spectrum for a.e. $\theta \in \mathbb{R}$.
- If $\lambda > 1$, $H_{\lambda,\alpha,\theta}$ has Anderson Localization (purely point spectrum with exponentially decaying eigenfunctions) for a.e. $\theta \in \mathbb{R}$.

Thus $\lambda = 1$ is a transition point.
Jitomirskaya’s conjecture:

In 1995, Jitomirskaya conjectured the following:

1. For $1 < \lambda < e^\beta$, the spectrum is purely singular continuous for all $\theta$.
2. For $\lambda > e^\beta$, the spectrum has AL for a.e. $\theta$.

Thus $\lambda = e^\beta$ is another transition point.
Phase transition with Liouvillean frequency

Theorem (Avila, online)

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$, then $H_{\lambda,\alpha,\theta}$ has purely absolutely continuous spectrum for all $\theta$ if $|\lambda| < 1$.

Theorem (Avila-Y-Zhou)

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$ with $0 < \beta(\alpha) < \infty$, then we have the following:

1. If $1 \leq |\lambda| < e^{\beta}$, then $H_{\lambda,\alpha,\theta}$ has purely singular continuous spectrum for all $\theta$.
2. If $|\lambda| > e^{\beta}$, then $H_{\lambda,\alpha,\theta}$ has Anderson Localization for a.e. $\theta$. 
Phase transition at $\lambda = e^{\beta(\alpha)}$
Absolutely continuous spectrum

- In the subcritical regime $|\lambda| < 1$, the spectrum has absolutely continuous spectrum.
- Jitomirskaya [Ann of Math, 1999]: If $\alpha \in DC$, $H_{\lambda,\alpha,\theta}$ has purely absolutely continuous spectrum for a.e. $\theta \in \mathbb{R}$.
- Avila-Jitomirskaya [JEMS, 2010]: If $\alpha$ is Diophantine, then $H_{\lambda,\alpha,\theta}$ is purely absolutely continuous for all $\theta \in \mathbb{R}$.
- Avila-Damanik [Invent 2008]: If $\beta > 0$, $H_{\lambda,\alpha,\theta}$ has purely absolutely continuous spectrum for a.e. $\theta \in \mathbb{R}$.
- Avila: If $\alpha \in \mathbb{R}/\mathbb{Q}$, then $H_{\lambda,\alpha,\theta}$ is purely absolutely continuous for all $\theta \in \mathbb{R}$. 
Anderson localization

- Jitomirskaya [Ann of Math, 1999]: If $\alpha \in DC$, $|\lambda| > 1$, then $H_{\lambda, \alpha, \theta}$ has AL for a.e. $\theta \in \mathbb{R}$.
- Avila-Jitomirskaya [Ann of Math, 2009]: If $\lambda > e^{\frac{16}{9}} \beta$, then $H_{\lambda, \alpha, \theta}$ has AL for a.e. $\theta \in \mathbb{R}$.
- Is there any new method to prove Anderson localization?
More on Aubry duality

- $H_{\lambda, \alpha, \theta} u = Eu \iff \hat{H}_{\lambda, \alpha, \phi} v = \frac{E}{\lambda} v$
- Bloch wave (reducibility) $\iff$ eigenvalue
- a.c for a.e. $\theta$ $\iff$ p.p for a.e. $\phi$
- reducibility for "full measure" $E \iff$ AL for a.e. $\phi$
- reducibility for "full measure" $E \implies$ AL for a.e. $\phi$
Full measure reducibility

Theorem (Avila-Y-Zhou)

Let $\alpha \in \mathbb{R} \setminus \mathbb{Q}$ with $\beta(\alpha) > 0$, if $\lambda > e^{\beta}$, $\rho(\alpha, S^{2\lambda^{-1} \cos}_E)$ is Diophantine w.r.t. $\alpha$, then $(\alpha, S^{2\lambda^{-1} \cos}_E)$ is reducible.

- If $\lambda > 1$, $\rho(\alpha, S^{2\lambda^{-1} \cos}_E)$ is Diophantine w.r.t. $\alpha$, then $(\alpha, S^{2\lambda^{-1} \cos}_E)$ is rotations reducible in any strip $|Imx| < \ln \lambda$.
- ARC + local rotations reducibility.
- If $\lambda > e^{\beta}$, the cocycle is in fact reducible.
Anderson localization

**Theorem (Y-Zhou, 2013 CMP)**

Let $\alpha \in \mathbb{R}\setminus\mathbb{Q}$ be such that $\beta(\alpha) < \infty$, if $\lambda > Ce^\beta$, with $C$ large enough, then for a.e. $\phi$, the eigenvalues of $H_{\lambda,\alpha,\phi}$ is dense in the spectrum, moreover, the eigenfunctions decay exponentially.

1. Topological argument + Aubry duality
2. Check the proof carefully, one can already get $C = 1$.
3. How to get pure point spectrum: complete eigenfunctions in $l^2(\mathbb{Z})$?
Anderson localization

Theorem (Avila-Y-Zhou)

\( \alpha \in \mathbb{R} \setminus \mathbb{Q} \) be such that \( \beta(\alpha) < \infty \), if \( \lambda > e^{\beta} \), \( H_{\lambda, \alpha, \phi} \) has Anderson localization for a.e. \( \phi \).

Proof: Study the distribution of the eigenfunctions, by Aubry duality, which can be analyzed by quantitative full measure reducibility.
Gordon’s lemma (periodic approximation) help us to exclude the point spectrum.

Avron-Simon [Bull A.M.S, 1982]: If $\beta(\alpha) = \infty$, then $H_{\lambda,\alpha,\theta}$ has no eigenvalues for any $\theta \in \mathbb{R}$.

Gordon’s lemma + Kotani’s theory: $1 < \lambda < e^{\frac{\beta}{2}}$, $H_{\lambda,\theta,\alpha}$ has purely singular continuous spectrum for any $\theta \in \mathbb{T}$.

Reason to obtain $e^{\frac{\beta}{2}}$: approximate the solution by periodic ones along double periods.
Singular continuous spectrum

**Theorem (Avila-Y-Zhou)**

Let \( \alpha \in \mathbb{R} \setminus \mathbb{Q} \) with \( 0 < \beta(\alpha) \leq \infty \). If \( 1 \leq \lambda < e^\beta \), then \( H_{\lambda, \theta, \alpha} \) has purely singular continuous spectrum for any \( \theta \in \mathbb{T} \).

**Proof:** Generalized Gordon Lemma.
Thanks!
